I've goggled electret mics and see that most of them have a built-in transistor amplifier. Although I've found the specs for the H10-10.34, I haven't found any information on its specific circuit or direct interchangeability with the H10-10. In any case, I see no provision for a built-in battery.

Mike –

What are you plug it into? A carbon mike, in majority of circuits will have to have DC on it, as the mike itself is just a variable resistor that has a resistance proportional to your audio. An electret mike also needs a bias, and often there is a battery installed in

the mike itself. I have never seen a David Clark headset with a carbon mike. Tell us more. 73 – Mike

□

I don't know if this is the right group to address my question to, but there seem to be folks here who are knowledgeable about microphones and such, so here is my question:

Is an electret mic. interchangeable with a carbon mic.?

I have a David Clark headset with a carbon boom-mic. and just acquired another David Clark headset, with an electret boom-mic., at a ham swap meet. The carbon mic. works well, but I'm reluctant to plug in the electret mic. in place of the carbon mic. for fear of ruining something.

Mike: N4FS is right.Carbon mics will have voltage & current flowing thru them that would not be needed or good for an electret mic. Electrets are condenser mics that are usually self polarized. Some condsener mics use a small battery, or phantom power (usually 48VDC) but the smaller electrets like you have are permanently polarized. You could install a transformer in your rig to isolate the mic from the circuit. What radios are you planning on using this D/C headset with?TNX, Mike, K4TQF

Today I jumpered the HV from the 275 pin to the 500 pin to do a low power test on the TX. Warmed it up then tuned as per online manual and tuned a small portable to same freq. Triggered the press to talk pin with a small screwdriver and instant success. Carrier in nearby RX. I had it on RT so I wouldn't need the key. Also tried it on SSB with the BFO (Het osc) ActuallyI like the receiver. It is reliable and solid performer. So I started making the six pin connector to mate to my vibrator supply. When i was a young lad and had my No 11 sets I used to keep a car battery in the basement on a trickle charger to run the no 11 dynoMtrs Never had a problem so i have a solar panel and a deep cycle 12 volt downstairs and i think I will just send a wire from it to the shack so I can have hi amp 12 volt available all the time. Raided the rough set for a knob as well so now this set is complete.

Making cable connectors is not my idea of fun however I have the end discs drilled and made from thick plastic. I raided an old wafer socket for connectors to contact the pins. That was enough for today.I have to put it all together in the hole sealing it so there are no leaks and pour the assembly with epoxy. I have a plan . Here is hoping it works. I am only doing the power connector for now. I will get creative with the control connections. My main goal is not to damage or butcher the radio proper in anyway. Been in touch with KD6TKX. He has been working up to 400 miles with his WS 19 barefoot. I could live with that however I ran into a fellow using one to push a SB200 so I can probably use this one on my twin 811A linear for a slight gain. I know with the DX 60B I can cut it way back and still get good output. Also with the ARC5s. Apparently these Ws19s have some odd type of grid modulation. I have been studying the schematic but need to do more. I wont however monkey with the MK11 as it is in too good a condition. The rough one though, a MkIII is fair game I think.

I really do not remember how well the 19 set output drives a speaker. I has been over 20 years since I used it. Initially I used it with the original headset and microphone combination, however, I am not much for headsets, and I usually route the audio from my military sets through an commercial audio amp and then to nice big speakers. So, I assume that is what I did with the 19 set. 73 – Mike

This is going to sound impossible and maybe it interests no one else but I think you will see why it interests me and will allow me. I have been digging into No 19 history. The radios were designed by PYE of England at the beginning of WWII at the request of the British Military. My Dad fell in love with them while teaching wireless mechanics (radio repair) at No 1 Wireless School in Canada during WWII HOWEVER in the 1960s my Dad was Chief Engineer of PYE Canada. I don't know if he knew the No 19 was a PYE design but I intend to ask him. So then I read the story of the Canadian No 19 set which my operational set is and they are clearly marked as such. It told how they were redesgned to suit the Canadian military plus a few "fixes" the sets needed and how a group four engineers from competing Canadian firms went together on the redesign and flew to PYE to learn the manufacture and come up witha suitable modified design for Canadian use. Canadian sets are different in some ways but compatable with UK sets.One of the engineers and the only one mentioned by name was the late Sydney Stillitoe of Belleville Ontario and he was with Northern Electric. I live at Belleville Ontario and my mailing address is RR#1 Belleville Ontario, My cousin Ken Dulmage worked at Northern Electric till it shut down manufacturing and my brother in law was the stationary engineer at the plant for one of the shifts for many many years. I think this radio belongs here. Spooky to say the least.

Connector made and cabling done to mate with all my shack supplies. I use always a 7AC octal socket pinout for power supplies so I can run anything on any one.PS If 12 volt I use pins 7 for grd and pin 6 normal unused for 12V+ on heaters. For hv for PA tubes I use the screen pin (4) By keeping a convention I keep out of trouble. However I have decided to run this set totally battery power and have a PS made from a 57 ford car radio PS then all I have to do is keep an deep cycle 12v battery charged and hum is a non issue. (There goes my best worst signal award !) And yes No 19 set runs a speaker easily. Just tried it a few minutes ago. I don't know the impedance output of its audio but will find out before suppertime. These sets used to be run in carts with four 170 AMP Hr batteries so A 900 amp deep cycle should give me all the time I need. Set B+ is not heavy but heaters are. Cw section works well. Going to try phone after lunch.

Up and running. Found proper speaker impedance and also use speaker and audio transformer for a dynamic mic. Seems to be well suited to the rig. The rig runs the twin 811A linear even at 1/2 PA voltage. Am for all intents and purposes good to go. Need to build a 500 volt vibrator supply but will probably do a 700 volt since the 807 can survive that(run my 1625s at 770v and have for a few years) Going to install the control switch (TX PTT, Speaker or mic input and Rx antenna) in the speaker box. One switch and 5 wires should be easy. Been on 40M testing today. It has been fun. I am sorry but I forget who gave us the heads up on these radios but I owe you a big thanks. Back then I gave the owner a promise if they didn't sell at his price which was decent I would at least give him xxx rather then see them scrapped. After several weeks of playing a thousand questions and no hard cash he just said "their yours if your deal still stands." I am from old school where a promise made is a debt unpaid so I antied up immediately. We shipped them by bus with shipping cost collect. Shipping was under $60 for both which is a lot less then driving there. Turns out he had worked with friends who used to live there and now live here that we have Sunday lunch with every weekend. Small world. Anyway whoever gave us the Kijiji heads up, thanks!

To power my ws19 set I used a 12 volt vibrator power supply I made several years ago from a discarded 57 ford radio. I needed a quick portable Hi voltage supply and a friend and former student gave it to me. I hacked the PS corner out of he defunct radio and have been using it from time to time on a 12 v gel cell. It runs the No 19 with ease , even the Tx but on 1/2 power for the PA however it does work. It is quiet on Rx anyway and I am very happy with it.In fact I should be using it on my 29 style rigs. I had purchased a solid state vibrator and have a socket and transformer etc for a decent HD PS. That I can handle but dumb as it may seem I dont know how to wire the vibrator and since this one is solid state I would probably only get one chance. I could take the one I have out of its box but when I built the box I used instrument glue methods to make it and so it would get destroyed in the process. Seems wasteful. I searched on line for the vib pinout and found several people asking as well but none not one actual answer. I dont want to know how it works, if it is a good or bad idea, will it or wont it work or was it original. I simply need to know which pins are which. Two fat ones (probably 12v but I dont really know) and two thin ones Probably 12v ac output.) There is a lot of experience on this site . can someone help me with the pinout for these. I still cant believe it wasn't easily found.

Let me rephrase that then. the question I am asking is not how they work. I am very aware of that and the circiut diagrams and PS styles. what |i needed to know was the vibrator pinout. Just the same as one might want the pinout for a 12sa7 tube for instance. I found that this afternoon. I always want to know how everything works and spend whatever it takes to find out.

OK, Don.

The reason I thought the schematics would help is because I assumed if you were familiar with the common vibrator supply circuits, you would just trace out the connections in your supply, and deduce the vibrator pin-out from that information. (That is what I would do, and have done in the past.)

Anyway, in an earlier email I had sent a sheet with the pin-out information, and another sheet which I thought might help you determine which vibrator you had, because of the relatively large number of vibrator types and different pin-outs. Did you see it?

Last summer I was working on getting an old tube-type Regency MonitorRadio going; this is a mobile VHF NBFM receiver for about 152 - 175 MHz. It had a vibrator B+ supply and the vibrator was dead. I made up a plug-in solid-state replacement - a simple multivibrator circuit with a pair of NPN power transistors - and got it working.

Yeah I coulda traced my other supply. I never thought the pinout would be not readily available. Thanks for the info. I have a Antique Electronic supply solid state 12v replacement. non schnro style(need a rectifier tube or set.) I also have a Dynamotor and am tempted to run it instead. I also have a set of the old power transistors that were used to replace the vib circuits years ago. Right now I am hunting for a useable transformer. I will have to kill one of my AC supplies I guess to get one. OR I could dump the rectifier tube, insert a set of diodes and pull of some ac as well to feed a doubler for the 807. At the moment a proper transformer is the obstacle.
If I build this stout enough I can also run my ARC5 on it. But I don't want to spend any money.
I am pleasantly surprised by the No 19 set. Normally as you know I monitor on a beverage and a HR10B. The beverage was for years a huge advantage but the No 19 can hear everything it hears and cleaerr on a normal antenna that I use for TXing. Selectivity is nothing to write home about but an HR10B isnt that great either and if conditions were bad no one would hear me from here anyway.

Anyone know a source for these? Kimco has them.. Tks Steve...

http://gokimco.com/small-nut-starter.html?gclid=CL-coLH1gMQCFZKGaQodf5YAfQ

preventing the wood from shrinking? Gads! You mean the paraffin treatment is bunk?! Held for the first 5 years. I'll try bees wax. Wonder if soaking it in thinned lacquer wood do it?

Anyone else?

> Do you have a kink for preventing the wood from shrinking?

use kiln-dried wood...you could also bake it at the lowest temperature that your toaster oven will allow...for several hours. I've never seen the coil form shrink after winding although I have only used kiln-dried.

Very limited as to what I can find here. Oven method best bet. Thank you, Steve, GN, Lou

I wind most of my RFC including HV plate chokes on hardwood doweling which is dry and hard. Never ever had an issue. Shrink? I am betting you couldn't measure any shrink with a micrometer even. Many of the wood treatment ideas are based in urban myth. Depend more on the type of wood then anything else. I know you read and heard but I am in another life a instrument maker (fiddle maker) so am used to wanting no shrinking no cracking a very low moisture. Hard maple is very good as are some exotics. Hardwood doweling is in most cases sufficiently dry to varnish and use right way. I learned to use maple by a fellow who made a telescope focusing device accurate to 2 millions of an inch. He is a friend and mech engineer. He has a lot of hands on hobbies. He made that whole device out of hard maple. Doesn't warp doesn't shrink , isnt temp sensitive was his reasons. Since that time I have used a lot of it. The Ontario Science Centre borrowed his device to focus their telescope. It was more accurate then their own. The right wood is the key.

I finally finished my No 19 connectors and cabling. I would prefer to have originals but I am told that is no longer possible so I made them from available materiels.
My vibrator supply sits to the left and the speaker /microphone is above at the end of the brown control/audio cable. It works pretty good on rx although I have yet to have a QSO.
meanwhile above another project sits awaiting completion. A 45 Hartley cathode modulated by a 01A and period correct audio transformer for its carbon mic circuit. All of this has been built before and operated independently. I am now putting it all on one chassis.

Man you have sharp eyes for an old lad! Same power out as AM so it is pretty light but that shouldnt be a problem. 80M at time of your choosing. Probably 3615 your favourite spot. I am tuned up on 80M barefoot currently. Would probably start off on Cw and then switch to MCW. Speaking of you we were talking the other day about 160M , 1945 to be specific. Even though the rig is only calibrated 2 to 4.5 on the low band there is quite a edge to the dial. I suspected like most it might go beyond so I set my digital to 1950kc (which is my significant number) and tried. I was able to reach it with ease. I didnt take the time to find how far it would go but I would guess perhaps 1930Kcs. So 80M 40M and wee bit of 160M. Then there is the VHF B set as well. 235 mcs.Some fellows have squeezed the coil to put it on the 220 mcs ham band. Some are rewinding a coil 10 turn centre tap 3/8 inch to get 144mcs. Me I am going to see if on my spare set I can make a 10meter coil work. If so I would change the dial to 28.5 instead of 235 and have almost a 1/2 watt of 10M am. Back in the day 10M was considered VHF according to some of my old handbooks and so they used these oddball circuits for low power AM rigs. Not a huge difference from a Heathkit twoer or tener. Otherwise I will just leave the B set alone. 220mcs for me would be a waste of time. I have a Heathkit twoer so that would be not required but a QRPP 10M AM rig might be fun. I think power out is .4 watts.
All in all a lot of radios in one box and then there is the intercom. Why you could use the HF set to generate a carrier . drive a linear and use the intercom to modulate the linear. I know , I 'm nuts.
Anyway at your convenience we can try the MCW.

I learned a few things in the last two weeks. One is the sets do not like carbon or crystal mics but need a moving coil mic to work best. Huge difference. I made one up old school style from a speaker and an audio transformer 3 to 1 approx ratio. It works well. You probably have all the original stuff so this may mean zip to you. They are noted for having good audio so I found out. Ifyou want to test Cw and that isnt your thing. you could learn your call and a serious of Vs ...- ...- ...- and the fellow listening would know you are testing and you have identified. And if it was me listening you would have no troubles to worry about. just say where and when. They used to sell code readers back in the day. MFJ was one. Whether there is a computer equivalent I dont know. I have an original Kantronics teletype/code system for a VIc 20 (even have the vic 20) from the seventies. I used it for teletype and mail boxes , the prerunner for todays internet but I did try it on Cw a couple of times and it worked perfectly. You could also send CQ and your call with it automatically which was neat. The Vic 20 quit but the Kantronics never even had a hickup. There must be something similar today. Used to live in VE2land in my teens (Pointe Claire, Dollard and Pierrefonds) In fact was kicked out of house and home at 16 and cast adrift in a sea of fun and crime there (1967) I had neither.

The 160M AM net on Monday evenings at 8PM on 1945 KHz is SSB but will certainly take check-ins on AM if they can be heard.

There is also the Grey Hair Net on the same frequency at 8:00PM Tuesday evenings which is all AM.

No reason why it can't be done with a little time and effort. There's plenty of multi-mode software out there to send and receive various digital modes, and the ones I've run in to usually have CW. The hardest part is the interface from the computer's serial port (probably a USB port these days) to key the transmitter. As far as receiving goes, just sample the received audio and poke it into the sound card; the software does the rest.

It would be a fun exercise, but, OTOH, it may kind of spoil the WS19 "experience."

I realized I didn't know what MCW sounds like either Lou so I just tried it listening on a AM rx without BFO on it. It sounds like a typical code practice oscillator. In fact what comes through on the sets speaker is identical to what is heard on a nearby receiver. I also heard a Ham across the lake (Lake Ontario)testing. I gave it a shot on AM even though still on low 250 volts on the PA at the time. He could hear me say his call but we didnt have enough to have a QSO. He said I was just below average noise floor. I am happy with that for now. At least it works. And an hour later I managed to add the extra voltage to the PA tube so I am probably up to 4 watts out on a good day! I suspect at these power levels on a good day he could hear me fine.

1945kcs is easy and power is decent there. About the same as on 80M. Maybe 4 to 4.5 watts output. (7.5 watt dummy load light bulb bright yellow.) Rig will tune as low as 1885kcs but isn't super there. Last few KCs down the PA tuning loses the carrier freq some so I think 1900kc is the practical limit. I now have about 480 volts on the PA. I series stacked the second supply which solved my transformer problem and it all works well. 230volts on the RX and main Tx and an additional 250v stacked above feeding the 807 final. So 480v HT2 or 480v ground to 807 plate. Spec calls for 500v. I imagine 600 would be even better. I would try even more but the meter is only 600v so I don't want to hurt the radio or modify it in any way. Certainly enough power to drive my linear into reasonable power in decent conditions. Although I cant drive my linear on 160M so I may have to use my ARC5 160M rig down there. Man I have had a load of fun with this rig so far.
Gonna sell my Heathkit station.

Net control stations rotate week-to-week and are in CT, MA, or ME. But we have check-ins from upstate NY, sometimes western NY.

Hello All, - This is truly a wonderful document you'll want to look at. It's chock full of Amateur Radio apparatus information from 1921 including some circuits, etc etc.

Best regards,
Joe

Pick up your copy here: http://www.skywaves.ar88.net/Docs/default.html

Many thanks to Joe, N3IBX, for being patient while I copied his truly wonderful document.

I have been working on this steadily. I got tired of the rain barrel sound of a speaker mic so sorted through the dozen or so mic and mic elements I have here and found one that really seems to suit the No 19 well. I didn't have a holder so I made one out of ABS plumbing parts which can be considered faux bakelite. Came out pretty good. The HT! (low high voltage) fades during transmit because I was stacking two 300 volt supplies taking HT1 of the top of the bottom one and adding HT2 (PA tube Hi voltage) I am working on a stand lone AC supply the handles both and the heaters easily. Am also working on a HT2 vibrator supply but am waiting for a suitable transformer. I prefer to run this set from 12 volts and have hooked up my emergency solar power to a deep cycle battery which is always on charge when the sun shines. I then fed the 12 volts into the downstairs shack. I have gotten power levels to the high side of specs on AM and have also tried it driving my 811A linear which is does easily. I prefer though to run it barefoot. I am really enjoying this radio. Band conditions have not been that great lately when I have been on so I haven't had a real good QSO on it yet but have had enough responses to know it is getting out. Other then a quick test I haven't tried it on CW yet.
Didn't plan to enjoy it so much. There is a huge world wide support for these sets. I am surprised at the resources available and folks are using them too, not just polishing them.

Hi,
A lot of these type caps have been around since the days of WW2 surplus. Often they have a 6-32 threaded brass insert at each end. I'm guessing yours may be the type "CM-60". They were made by Sangamo, Aerovox, Cornell-Dubileer and others.
I'm guessing that the 5KV may be the test voltage but that is strictly a guess.

CUL, Roger/K1TG

With the Mk11 up and running well I turned to the MkIII set which is very rough. It may still work though and is certainly repairable. I was missing a 6v6G and the 807 final. I dont have any of the old big 6v6g tubes so I am popping them out and putting in a matched pair of 6l6EH tall boys. I won't get any advantage because voltages are for 6v6g tubes but they are matched and will work just fine. I dont have any 807 tubes but have a dozen 829B which are basically a 807 pair. I can make an adapter socket easily and since the is radio is so rough hot rodding it a bit wont bother me as much. I have done similar deals with 829B tubes before and have one with an octal pattern I made to replace a 6146B. In fact I had it going last month. Current draw on the heater is more but I think it should be ok. If not I can find a work around. I am having difficulyt finding the MKIII power and control socket pinouts. I may have to resort to my old trick of feeding the pins with clip,leads and a 9 volt battery and seeing where the voltage goes, then labeling them. That way nothing gets hurt and I figure it out.

I have several of those in my pile. Some are marked 5000 VDC, others B.D.T. 5000 V. They all look identical so I am guessing breakdown voltage.

I'm reasonably certain I have, somewhere in my collection of files, an ad from back in the day which mentions the high voltage versions of these (I believe there is a 2500V in addition to the 5000V). It may provide more information if I can locate it.

Thanks Jim for the offer but this radio is too far gone. Amazing when you put your glasses on what you find. It looked pretty good when I couldn't see. Bottom line is I got one real nice good working radio in the deal, the MK11 Canadian and this will serve for spare parts if I need them. However I was fooling around looking at the B set section (vhf 235mcs AM simple tx and supergenny combined) I had heard of folks bringing them down to 220Mcs ham band and was able to do that by squeezing the coil spacing. (high side of band)I had heard of folks making a 144mc coil for the rig but I already have a heathkit twoer lunchbox. 6m sounded attractive so I took my GDO which goes to 250mcs and popped in the 45 to 100 coil. At 11 turns I was able to hit the 6M band full on. I will solder it in and test it on this derilect set since there is little to this part of the set. If it works and receives ok I may do the mod carefully to the No 19 MK11 so I would be good on 160M 80M 40M and 6M. It may not be practical but since the B set is almost another standalone rig I can try it for fun and see if it has any merit. It is only .4 watts so not really too useful but it could be fun anyway. Meanwhile I am waiting for some good propagation so I can work NE1S on 7290kcs barefoot.

I brought my two tube LW regen upstairs and hooked it up today. I could hear the Trenton beacon today but tonight lots of signals. One YMW reportedly is Maniwacki Quebec.
I am hoping Steve can shed some light on it. I suspect a marine beacon but don't know. Also heard some faint CW of message style much lower in the band. I tune approx 300 to 500kcs. I need to improve the volume on this set a bit. It is different somehow listening on longwave. Why I don't know but it is. Almost spooky.

It's an NDB about 4 miles from the Maniwaki Airport. Odd that you should mention it as I also mentioned it and have a recording of it on my blog today...heard here on Tuesday night....it's a 500 watter.

Thanks. I was surprised so many signals. However judging from the Trenton beacon the rig is not real happy on the sort of beverage antenna I had it on. I will have to play around with my other upstairs antennas and see which it likes better for now. Downstairs I had hooked it up to my 80M longwire which is simply the very best ham radio antenna I have ever had up. I don't usually listen on it but it was quick and easy however last nights experiment upstairs has me thinking. I need to come up with a good LW antenna up here but something not too complicated. Not sorry I built the regen. Free built (no schematic or plan)and from my junk box I don't have a dime invested and I am already having dollars worth of fun. It is always fun exploring new frontiers in the hobby. I found the bit on the Oshawa Airport beacon interesting. It will be intriguing to see what the actual power really is. Because if it is as stated then It is possible I could build a low power tx and do some CW in the ham portion of the band. Maybe a 6l6 quad four final with a 6ag7 osc

I was on just before lunch here on the No Net 40M net I believe they called it. I believe net control said he was in CT but I may be wrong because I was a bit excited. They had been discussing BC series Aircraft sets and old militry sets in general just before the net call and I was listening on the No 19 (which has very good ears on 40M) the vibrator power supply singing merrily away hooked to the solar charged deep cycle battery in the next room. He said any further check ins? I had nothing to lose so threw the switch and spoke into the mic. I got them. He asked what I was running I said a no 19 barefoot about 6 watts out. He at one point gave me a 10 over report and even if that was over generous obviously I was getting there. I didn't hear Larry in there but asked them to make sure they told NE1S that VE3LYX was in on the no 19 looking for him. I am surprised and conditions were not terrible but not great either with a fair amount of background noise.(maybe S3 or S4 constant) I finished the conversation and excused myself as my HT2 (PA plate voltage) was starting to sag as the battery protested its mornings long workout. I am enjoying this radio and sit here wondering what to do with the Heathkit DX60B and HR10B. Somehow they just dont fit in anymore.Something about running a 70 year old transceiver that is just a lot of fun. I don't know the distance because I forgot already net controls call. (dropped my pencil cause my hands were shaking with excitement.)Probably around 350 miles or so I think. Anyway maybe next try some of you east coast guys will be there.

We'll catch up I am sure. It was Clark I was talking to I believe. He isnt as far away as I thought. Only about 282 miles but that is about 100 more then my last (and first with the No 19)
I got lucky today. My brother was cleaning out his basement and asked if I could use 4 old vibrator radios no charge. Just picked them up. Three 6volts and one 12v. One has a pretty good looking transformer and is the 12V. I see a new PS in my future!

I am surrounded by vibrator power supplies mostly put together from old car radios of the fifties. Some 6 v and some 12v. While they all work they simply don't have enough iron to handle a heavy load. When I switch to transmit now that i have optimized my No 19 with a antenna matcher and such it really grunts on TX and I lose at least 50 volts of my main HT voltage. Still works and I have worked some dx of sorts but it not the way I want it. I am on the hunt for a proper Vib supply for my No 19 as that is what Canadian troops used. However I have all these neat little supplies and they work well. I decided to convert one to use on my Hartley. The idea of battery power on the heater appeals to me. I had to get a bit creative to seperate the heater (6 volt supply) and cathode supply which are both grounded in the vib supply. Now the cathode is free and the b- is fed through a pair of low ohmage resistors same as my TNT. It is also keyed. Now I have the deal working and I can kiss my best worst signal award goodbye. Since I am preparing to loop with Lou (if the sun ever settles down and gives us some good prop)I also taped my mic PTTdown and rigged my mic so I dont touch it or hold it thereby eliminating one of the big drawbacks of the system. (no touchy no wiggly). (Lou hung his in front of himself) A 6v spotlight gel cell tuns the whole deal well surprisingly.

I am having a great week. Tonight I went down to my basement shack to make sure everything was turned off. while i was putting stuff away I flipped on the No 19 and was reading the mail as i worked. I heard Frank K3SQP talking to a New York station (--vwp?) just as the NY station stepped aside to take a phone call he asked if anyone else was out there. Steve (I wrote his call down wrong. He likes to talk about fishing) came back and then Frank asked him to drag his feet on the changeover. I hit the Hi voltage (HT2)supply switch and gave it a shot. Bingo. Had a bit of an exchange with both of them. I think Steve said he was in Mass and Frank is in Pittsburg PA. I can hardly believe this. I am running barefoot! 6 or 7 watts tops. I don't get any better results with my Dx60B. Sorry to get so cranked up but I am having a ball with this old rig!

I was playing around with my Hartley today and made a voice delivery tube allowing me to set the mic on the desk with the PTT taped on and speak into the tube eliminating the need to hold the mic and its cord. 14 inches seemed to work the best . 3 1/2 feet had an odd sound The shorter sounded little different from my normal method except the hand effect or body effect of holding something in the tuned circuit is gone. Now all we need is a good propagation, low noise day for a loop de loop with Lou. Eventually i would like to mount the mic in the set right at the tank and use the voice tube.

I am building a whimsical phone transmitter consisting of a parallel fed 203A Hartley with a 211 Heising modulator. I plan to run them both at 1250 volts on the plate with about 60% modulation.

I fired up the oscillator today with the modulator removed and varied the plate voltage from 1250 volts to 500 volts using a variac. I noted that the oscillator frequency changed by about 270 Hz, which seems quite high. When the plate voltage is not being modulated, the oscillator runs pretty stability and without appreciable chirp.

Some of you guys have stated that you have gotten your modulated oscillators to run with minimal FM. Care to share what you adjusted to specifically maximize the frequency stability during modulation?

go gentle, no more then necesary. find the spot were you can modulate to, that will not push you over the edge and stay below it. Stiff wires and short leads and for us I found under 5 watts out it was doable and that was all I wanted. My hi power hartley (211) was uncontrolalble above 600 volts and ran away with itself. But with heising and a bit of restaint you might pull it off if you tread lightly. We were and are stealing (absorbing)RF output power from going out the antenna rather then modulating the osc. If we were moding the osc we were pushing it too hard and increased spacing (or added an adjustable R in the mic circuit) so it didnt bother it. Your experience may be quite a bit different. Anyway, you asked, this is what I found.

Nice looking rig. The FM problem reminds me of the BC191/BC375 which is a modulated MOPA. A lot of guys got these working on the air, and had FM problems. The FM issue was almost completely eliminated by proper neutralization. I never did power mine up, and I have a nice one in the basement. Here is an excerpt about neutralizing the 191/375:

“Dynamic Neutralization - Probably the Most Important Step - The BC-375 is usually found without its matching serial number Tuning Units. This means that the "orphan" TUs were neutralized to a different BC-375 and will require neutralization to your BC-375. Any non-matching serial number TU that are to be used absolutely need to have their neutralization adjusted for minimum FMing. If the transmitter TU is not neutralized, then some minor parasitic feedback in the master oscillator will cause frequency instability, or FMing, causing more audio distortion. This parasitic feedback is made worst when the +HV is fluctuating with the load. The easiest neutralization method requires a receiver capable of FM detection that will tune to the BC-375 transmitter frequency. These types of receivers are always limited to more modern types of communications and SWL receivers. I use a Yaesu FRG-8800 which does have the capability of receiving FM on all frequencies. Tune in the transmitter's signal on the FM receiver and talk into the microphone. If the BC-375 is FM'ing, you will hear yourself quite easily. It's best to use earphones for monitoring. Adjust the TU neutralizing control until you no longer hear your voice modulation and the FM'ing and audio distortion should be at a minimum for that tuning unit at that frequency. You might have to adjust for the minimum audio response as voice peaks always seem to cause a little bit of FMing. The difference can be checked by switching the receiver over to AM detection and listening to yourself transmit. All of the "fuzzy" sounds should be gone and the AM signal should sound clear and intelligible. If you have the proper kind of FM detector-receiver, it's easy to check the neutralizing often and the results are simply amazing. There is no other easy way to set the neutralizing on the tuning units. NOTE 1: Even if you are using a +28vdc high current power source, you still need to do this neutralization to assure the transmitter doesn't distort because of parasitic oscillations. NOTE 2: I have tried other methods to set the neutralization for minimum FMing, like using a standard communications receiver with the BFO on and listen for deviations in the carrier frequency but this doesn't work at all. About the closest to FM monitoring is to use earphones to monitor your BC-375 AM signal on a standard communications receiver and adjust the neutralization for the best sounding audio. This will get you kind of close but not as close as the FM receiver does. Thanks to Tom Horsfall, WA6OPE for the dynamic neutralizing information using an HF FM receiver.”

Hi Mike,
Very interesting!
For those that have no access to an HF rcvr, with FM receive capability, I wonder if reasonably good results could be achieved by using an FM BC rcvr, to listen for the desired minimal FMig?

Hi Jon,

I made no attempt to optimize this. I just had a Hartley that was stable on CW, inserted my modulator (PP class AB2 45's through an old Kenyon mod xfmr) and it worked well, with minimal (albeit unquantified) FM). The only trick I used was to limit the negative peak excursions so that the oscillator wouldn't shut down on negative peaks wit the following circuit:

http://www.amwindow.org/tech/htm/3diodeka.htm

In my case I use a keep-alive voltage of about 24V with a DC plate voltage of 400V on both the Hartley and modulators (common B+ supply). The keep-alive voltage is off a voltage divider on the same supply. I am able to modulate in excess of 90% in the negative direction, and 100% (perhaps a bit more) on positive peaks.

You may or may not want to use such a circuit depending on your objectives for the project, as I'm sure it wasn't conceived in 1929. (It should be adaptable to single-ended Heising modulation.) Mercury vapor (vapour for Lou) rectifiers can be used as the diodes but you'll need at least two filament transformers to light them. Of course, if you don't exceed 60% modulation in the 1st place you won't need this at all.

Incidentally, I have a friend who runs plate-modulated oscillators who isn't concerned about stability or incidental FM, and he optimizes his oscillator for maximum power output, stability be damned. His tank circuits are not high-C (and are thus lower Q) and I suspect this may come to play in the result. He has a quite a bit of incidental FM. I think if you start with a well-built, stable oscillator you will also minimize the FM component.

73,
-Larry/NE1S

This a thought arising from the theory of Frequency Modulation that was triggered by Mike Feher's description of "dynamic neutralization" of his BC-375. I haven't tried this in practice so it may or may not be useful, but for you guys who are concerned about incidental FM during modulation, it could be useful.

Mathematical analysis of a sinusoidally modulated FM signal shows that it consists of a carrier of fixed frequency plus multiple upper and lower sidebands spaced from the carrier by an integral multiple of the modulation frequency. So for example, if you are modulating with a 1 kHz sinusoid, you will have sidebands at 1 kHz, 2 kHz, 3 KHz, etc above and below the carrier frequency. An AM signal will, as you know, have only one sideband at 1 kHz above and below the carrier under the same conditions.

If you had a selective AM receiver, something with a good crystal filter or a sufficiently narrow mechanical filter, and if you could supply a sinusoidal modulating signal from an audio oscillator - just whistling into a carbon mike probably would not do the job - you could tune into the second order sideband, at 2 kHz away from the carrier in our example, and adjust the BC375 neutralization or the audio level in case of a modulated oscillator rig, to null out that sideband. That would eliminate or minimize the FM portion of the signal, and it would not require an FM receiver to do the job as Mike described.

A long time ago when I was teaching EE at Ohio State and the eyes of my students had glazed over due to my blackboard presentation of FM involving Bessel Functions, I pulled an AM/FM signal generator out of the lab along with an HP audio oscillator and an HRO-60. We were able to tune in to the individual sidebands of both AM and FM signals and to see how those sidebands varied as we increased the modulation index of our FM signal. It worked beautifully. There are even levels of the modulation index where the carrier actually nulls out, and we were able to observe that happening, with nothing more for a detector than the HRO with its crystal filter in position 5 and by watching its S-meter.

Just a thought.

Hi Jim -

I cannot take credit for that method as I cut and pasted from the link that I provided. It was just that almost anyone I talked to using a BC-191/375 always had an FM issue till they did the neutralization.

It has been a long time ago but I do remember the good old Bessel functions. I used to use the Bessel zero crossing (nulling) to set the deviation of my 2 meter rigs back in the 70's.

the job as Mike described.

A long time ago when I was teaching EE at Ohio State and the eyes of my students had glazed over due to my blackboard presentation of FM involving Bessel Functions, I pulled an AM/FM signal generator out of the lab along with an HP audio oscillator and an HRO-60. We were able to tune in to the individual sidebands of both AM and FM signals and to see how those sidebands varied as we increased the modulation index of our FM signal. It worked beautifully. There are even levels of the modulation index where the carrier actually nulls out, and we were able to observe that happening, with nothing more for a detector than the HRO with its crystal filter in position 5 and by watching its S-meter.

Just a thought.

Great ideas, Jim. I too remember about learning about Bessel functions in my differential equations class, and their application in the frequency-domain analysis of FM in a communications engineering class.

Another useful tool would be a spectrum analyzer (which I don't have, or the spectrum display of an SDR (which I do have).

Thinking about the FM sidebands gave me another thought. I have had several phasing-type SSB exciters (which usually include PM as an available mode). When an audio tone is used for nulling the undesired sideband during alignment in USB and LSB modes, sometimes there are multiple sidebands at multiples of the modulating frequency. At first I chalked this up to driving an audio stage into saturation, creating harmonics, but I remember on at least one occasion they appeared immediately as the audio gain was increased from zilch right at the audio signal generator, i.e., prior to the 1st audio stage of the exciter. I wonder if the modulator could be producing some FM (or PM) even though the selected mode is SSB? Anyone else run into this?

11116. FM/PM from SSB phasing rig

Yahoo group: AWAGroup (2014 — 2016)
Date: 2015-03-24 18:49:09 UTC
From: JAMES HANLON
Topic: 11116 Message: 11116

Larry, NE1S, brought up an interesting topic, the PM signal that can be generated by the old, phasing-type balanced modulator SSB exciters.

So I just tried an experiment with my Central Electronics 100V, which can generate either USB, LSB or DSB (AM) with or without a carrier, CW, FSK, and also PM with carrier. I dug out an old Eico 378 Audio Generator - it makes decent audio sine waves and has a variable output from about .0005 volts up to 10 volts. I set the Eico for 2 kHz and hooked it up to the microphone input of the 100V, and I observed the spot/monitor output of the 100V under various settings of the Emission switch. I used my HRO-50 which has a 200 Hz mechanical filter in the IF for a "spectrum analyzer."

In all of the various AM/SSB emission settings, with and without carrier, I observed basically what you would expect. In particular on DSB plus carrier, traditional AM, I found the carrier, two sidebands, and a very low level set of second order sidebands that were probably the result of distortion in the Eico waveform or of nonlinearity in the 100V audio chain. When I switched to the PM emission setting I found the same thing as with the DSB AM mode, a carrier, two strong first-order sidebands, and two very weak second order sidebands. Switching back and forth between AM and PM I noted that both sets of sidebands were a bit stronger in the AM mode than in the PM mode, at least for the amount of audio drive I was using.

I found no trace of sidebands beyond the second order in the PM mode, even with substantially more audio drive from the Eico.

So I'd have to conclude that the PM modulation in this phasing rig is sort of a pseudo-PM that generates only the first-order sidebands but nothing beyond that. That's what I would expect, since the balanced modulators are generating, ideally, only first order sidebands and that you get the resultant DSB, SSB or PM signals by just varying the phase of the output of the balanced modulators as you combine their signals.

Jim, W8KGI

Speaking of PM etc I remember an article, may have been in an old CQ or 73 mag I read back in the day when men were still men and tubes were king, about an experiment on 2M with modulation by antenna polarization. (horizontal vrs vertical.) It produced quite a discussion. I am sure I kept the article because I liked so much the writer tried it in real life and got it to work. The big discussion was did it work because it was polarization modulation or was it actually a form of PM inadvertently. I found it very interesting at the time and never forgot it.

PM stands for phase modulation.

A general time-domain mathematical representation for either the
electric or magnetic component of an electromagnetic wave is:

A*cos(2*pi*f*t + theta)

A=amplitude
f = frequency in Hz
t = time in seconds
theta = phase angle in radians
(2*pi*f is also the "angular frequency," usually represented by a
lower-case omega)

varying A at an audio rate results in amplitude modulation (AM)
varying f at an audio rate results in frequency modulation (FM)
varying theta at an audio rate results in phase modulation (PM)

FM and PM are closely related and are both generally referred to as
"angular modulation." An FM detector can be used to receive PM, but the
recovered audio (IIRC) will be not be "flat" as it was transmitted - I
think higher frequencies are accentuated relative to lower ones, but
it's been a lifetime ago and I'm not positive. Applying the correct
frequency de-emphasis (or was it pre-emphasis?) curve to the audio
signal prior to the modulator would result in FM, or something very
close to it, out of a PM transmitter. Many years ago I used a homebrew
PM exciter to talk on 2M FM, without any tailoring of the audio response
curve. It worked.

To allow the 807 final and its driver more freedom in the former owners opinion. However, not every modification is as beneficial as intended or hoped. Most transmitters would not have that tube in them. It is not part of a normal circuit. However diodes, zener diodes are often used to prevent no signal runaway in an RF PA as I am sure you already know. Did you put your spare EF50 in yet? It would be interesting to know what the drive volts meter says with an active EF50 inserted. The online manual has a real good description of the EF50s function. It is on the QSL ws19 site and is for the MkIII set but still covers a lot more then I expected it would. I finally sat down and read the whole thing. 60 pages. Very informative.

Hi Don,

Yes I put in the spare EF50 and seems to align better than the original did. My drive is around 7 and I'm pretty sure that I could get it to go a bit higher if I sat there and continued tweaking. I still need to verify my alignment by grounding pin 5 of V2B the book says that when you ground pin 5 of V2B the drive should go to 0 or almost 0, if it goes up it means that the alignment is off. The problem is getting at pin 5 of V2B there is so much clutter of wires and components.. I'll keep you posted on my progress.

Awhile back, Jim, VE3BHK gave me a several 1920s junker broadcast sets. From these, and using whatever else on hand, I recently completed a "Depression Transmitter".

You know the story, unemployed, lots of time, but no money. For a dollar though you could buy defunct battery sets by the pile loaded with high quality variable condensers, Sangamos, tube sockets, UV-201As, 245s, and the occasional 210. ... or so the story goes.

Before the show begins I wish to thank, NE1S, WU2D, KK7UV, VE7SL and of course, VE3BHK for their help in this project.

From above and a junk box.

See photo below

The base
White oak with original finish, 1/2" X 61/2" X 18". From a striped Murdock Co. low power spark transmitter housing having the "instruments"
mounted on and within the box. Extra holes as found.

The RFC
Originally a tuning coil, unmodified turns. The mounting bracket was from a filament switch assembly.

Hook-up wire
#16 ga. Originally silk covered magnet wire, but the silk was rotten so remove the insulation.

Variable condensers
Tank shunt condenser - N.Y. Coil Co., ca. 1923-24
Grid - DeJur

Output tuning lamp with bypass switch.
Left in, the lamp absorbs 3/4 of a watt and makes for an interesting wandering signal.

Robertson head screws, a Canadian invention, their use found in mid-1920s BC sets manufactured in Toronto.
Also, they were on hand.

Results

At maximum recommended plate voltage (180V) the fully loaded output is 1.5 watts. At 250V B+, 4 watts out. With care in tuning the tone and signal stability are good.

73, Lou

Meanwhile in the Skunkworks here a replacement final tube has been made to replace the missing 807 in the rough No 19 which is not restorable anyway but still will power up. It is going to get hotrodded. The 829B tube is a conundrum as specs are not the same and confusing. For instance you will have no trouble finding people who have posted it is really two 807s and then someone will say no ,it is really two 6l6s but two posts later will hear a 807 is little more then a 6l6 with a plate cap so there is no voltage arc-over (not that there is anyway as I have had 600v on some of the 6l6EH tubes.)
Plate disapations often listed do not make sense and suppot neither position and then there is the fact that pops up that early production Viking ones had a 829B final as the USAF was hogging all the 4D32s. So in light of 1000 expert opinions and a few of recorded successful uses as 100watt input PA tube I have decided to make a 807 base 829B and actually try it. I have a dozen military pulls , some even Se29 tubes. The conversion was easy. Join the two grids, extend the pins with wires, find a old base and solder it on and pour the base full of epoxy. Might be a total disaster and I am ok with that. It will be fun trying whatever the result. I did two octal 829B conversions before and have had fire in them so that part I am ok with. Stay tuned

Hi Don,
IMHO, the 829 is not related to or comparable to a pair of 6L6s or a pair of 807s. (I have read from sources, that I considered reliable, that the 6L6 and the 807 are closely related, the latter being an upgraded, double ended version of the former, with internal shielding added).
AFAIK, the 829 is a unique VHF tube (oversized 832, perhaps?).
Based on my school of hard knocks education, with a smaller VHF dual tetrode, I would suggest installing a 33-47 ohm 1/2 watt resistor, in EACH control grid lead, and installing a separate parasitic suppressor, in EACH plate lead, of your 829, if you wish to avoid a serious VHF parasitic oscillation problem.

light of 1000 expert opinions and a few of recorded
successful uses as 100watt input PA tube I have decided to
make a 807 base 829B and actually try it. I have a dozen
military pulls , some even Se29 tubes. The conversion was
easy. Join the two grids, extend the pins with wires, find a
old base and solder it on and pour the base full of epoxy.
Might be a total disaster and I am ok with that. It will be
fun trying whatever the result. I did two octal 829B
conversions before and have had fire in them so that part I
am ok with. Stay tuned

I have run them both ways and have a 40M rig (829B final) with a split parasitic plus the octal pinned ones with single. So far so good but if I get even a hint parasitic I will switch. Since it will be a parallel pair it should have a bit more stabilty. I agree they are difficult to define properly. I guess there is one way to find out for sure. The Viking I thing is what keeps haunting me. They must have worked because EF J would not have used them Johnson is or was a company with a very good reputation. In fact in the 70s I owned a piece of a small company that sold and installed Johnson commercial two way. I used to look after the Alternator noise prevention and such up front in my capacity as a licensed Auto Tech and tune up specialist so we didn't have any issues. We never not once ever had a recall or set repair to deal with and it seems to me we were into it for about 4 years maybe 5. Re the Cont grids. Cant seperate the control grids now. All sealed up.However Kathode is joinedinternally as there really is only one, screens are joined inside so hopefully..... Anyway we shall see. I don't want to monkey with the chassis as I want this to be a plug in sub. The whole deal may be a big waste of time but I have the tubes and all required parts so why not would not bring a good answer. Also a B tube is a bit different then a straight 829 but I assume you meant an 829B anyway. The SE29s are very HD looking in through the glass. Time will tell I guess but I am saving your notes for reference if I have any troubles. Meanwhile I put the No 19 on the Linear twin 811A for the weekend.

Hi Don, Still not out of the woods yet I have a carrier but no voice, and my meter has the backwards modulation syndrome when its tuned to max scale deflection. maybe I'm doing something wrong in the drive alignment I'll check again. When you peaked your WS19 Mk2 in what position did you put C34A ?? The manual says to
align the two solder blobs.

I put the rig on my 7.5 watt dummy and trimmed the cap adjustment for max POWER output. It took very little to get there. Perhaps 1/8 of a turn. That modulation is characteristic of these rigs being control grid modulated which is very rare. My actual meter reading is no where nears yours but I get answers almost everytime. Because it is a voltmeter only meter readings are not what we expect as we are used to looking at grid and plate current. So in that case I get it up and running, Look for success and make note of normal readings in use. Then if something changes I know what to look for. I also work on the assumption that all of our radios where in service so the concept that they need a complete alignment etc etc is rejected in my thought process. The daily maintenance alone was quite good and if the set was bad it will have a "US" tag on it and one of mine does. Do you remember where it was before and can you get it back there. That is where I would start. I am not convinced that all "experts" have a working set on the air. BTW I can see the modulation plainly in my light bulb dummy load and can even compare mics. It is the most valuable weapon in my arsenal. I understand it and it never lies to me. Feel free to email. I went into this project blind as I had nothing but a radio in its case but have been learning as I go. What bothers me is you have a carrier and you have modulation showing on your meter but not making it out the antenna. When I have that on my Homebrews it means I dont have the tank or the antenna tuner tuned to the right freq. How that relates to our No 19s I dont know as so far I haven't had that on this set. I will dig further and see if I can figure it out.

11144. 40M AM rig

Yahoo group: AWAGroup (2014 — 2016)
Date: 2015-03-29 20:46:17 UTC
From: dulmagedon@...
Topic: 11144 Message: 11144
Attachments: 1 described; binary payloads are missing from this source WARC

Before Christmas I started poking away on a 40M rig cathode modulated. In the pic of my No 19 you can see it sitting behind the speaker. Today while waiting in hope for 40m to open up i was poking away and finished the transmitter proper. I have to install the Battery clips (holders) for the carbon mic bias and the jack for the mic but other then that it is pretty well finished. It is a 45 tube hartley and the cathode is controlled by a in series 01A. I am torn between leaving it as totally AM or installing a CW key jack. The two tubes will use independant heater supply sources which while inconvenient is not really a big deal. I have had all the circuit designs working on another rig but as separate add ons and it did ok. Now it is all one rig and all pre 1929 main pieces. I am hoping to find a candle stick phone to use as a mic once I have it up and running. Is there no end to this great hobby?:>)

Hello Don,

UPDATE!!!

I think I've got it!!!! I can hear my mod on my sw receiver, turns out that the variometer is at fault, its all screwed up. I put a Vectronics VC3000DLP antenna tuner it has 2 antenna ports so I can put the light bulb on port 2 and the outdoor ant on port 1. I also tweaked C34A about 1/8 clockwise.

So what frequency do you operate with your WS19??

11146. Johnson Viking I and the 4D32/829B

Yahoo group: AWAGroup (2014 — 2016)
Date: 2015-03-30 00:06:36 UTC
From: JAMES HANLON
Topic: 11146 Message: 11146

Guys,

There's been a bit of discussion about the Johnson Viking I and it's use of a 4D32 or an 829B in the final RF amplifier.

Back in the Viking I's day, from 1949 through 1952, the rig was sold as a kit, "Complete less tubes, crystals, key, mike" for $209.50. That left the purchaser of a Viking I kit to his own devices to acquire, in particular, the required set of tubes, which included three 6AU6s, two 807s, one each 6AQ5, 5R4, 5Z4, and 6AL5, and that all important 4D32. The 4D32 became quite scarce during the Korean War, June 1950 to July 1953, due to military usage. So the builder of a Viking I usually had to get creative about finding another tube to use in his/her rig. The most often used substitute was the 829B. The manual for the Viking I on BAMA even says, "While not capable of as much input as the 4D32, an 829B will work very nicely in the final stage. It will deliver at least 95 watts of CW output, 85 watts on phone while input is kept within the manufacturers' ratings." The Manual also contains a page describing "Typical operation using 829B final within ICAS tube ratings," and a page of "Changes required for use of 829B final amplifier." The 829B was an attractive substitute because it used the same tube socket as the 4D32, although the wiring was slightly different, and it was readily available on the surplus market for a very reasonable price.

At least one person made a different substitution, however. I have a Viking I in my collection which was beautifully built using a pair of 807s in parallel in the final. It was obviously constructed that way from the very beginning.

Then the Viking II came along in 1952 using a pair of 6146s, and the problem at least for purchasers of the new rig became solved.

Great!!!!!!!!!! Yes the variometer will not work properly on a proper ham antenna. The wartime manual even states that. You have it figured out. I use a similar deal with my system I have a HD coax switch and on one sid I have my light bulb socket with its coax and connector. On the other side is the antenna. I tune on the bulb and then switch. Of course on my little tuner the bulb socket is built in. A 7.5 watt bulb will do the job nicely on the No 19. Those are the little ones about the size of a golf ball but with a normal size base. I operate on 7290 mostly but can meet you anywhere if you want to test. I am suggesting 7285 but will go where you wish. The 40M and is good in the mornings till about 11.30 Am and in afternoon comes alive between 4 and 5 oclock. You choose. Congratulations on your success! Should be fun if we pull it off!

Yes tis as I understood.
My first rig was BTW a Viking II CD model (full coverage government issue) Worked an awful lot of CW with it for about 2 years. Other then its weight it was a great rig. I still run a pair of 6146Bs in my upstairs rig. KNWD TS830S.
However there is no argument , right? that the 829B was used in some Viking 1s, and could handle I believe you said up to 85 watts on phone? We know a 6L6 could not do that. Even a pair would be hard pressed. A pair of 807 would easily exceed that. I am sure you wouldn't disagree. I am using this tube because I have a dozen and have experience rebasing them. In this rig which has a single 807 and the rig is unrestorable (due to rust and abuse) to a collectors level. I can sub the 829B with its now 807 base directly into the no 19 chassis. The voltages used in this set are very similar to the 829B requirements so that it perhaps at least in appearance is easy. Other then making the heater 12v so it wont unbalance the heater current draws significantly (affect other tubes inadvertently heater currentwise) it is a plug and play deal. Whether it works or not I will know soon enough. What if I could use any tube and any voltage? I pop in a 813 and use the built in intercom mic and amp to modulate it. Would have to update the driver tube too I am sure however I don't want to physiscaly change anything in this set so this works and out of pocket 0$. Simply an experiment which from which I will learn something good or bad. I am up for either. The current set puts out its rated 5 watts of AM which is pretty dang low for even a single 807. I managed to get my other No 19 to almost 7 with some tweaking and a good ATU. If I could get 10 or 15 just using this tube it would be nice and something others could do without ruining their sets. I had arrived at the point I wanted to find out for sure as we all know that a good as plans are they are not the final judge one way or the other. One only has to watch a couple of episodes of mythbusters to learn that if it is not already known. Real life testing is the final judge. And besides it is a lot of fun! Some would ask "What if it doesn't work?" I think "What if it does?!" Anyway that is the reason behind its choice good or bad.

James, I gave the 6146B a hard thought and that could still happen but I didn't want to spend the rest of my days wondering about how a 829B would work. What I really need to do is set down with a bit of self discipline and figure how how they got a 807 to only put out 5 watts AM. I wonder why they didnt just use a 6l6 or even a 6v6 for a final if they wanted to limit range. There is Canadian Amplifier for these sets with a single 813 but they are rare as hens teeth. Anyway, we shall see what happens.

Don,

What type of AM modulation is used in the WS19? 5W carrier out would be very low for plate modulation, but sounds about right if control grid of screen grid modulation is used, or if the 807 is operated as a linear amplifier with modulation in a preceding stage (although I doubt they would do the latter). I once control-grid-modulated an 807 and got about 7W of carrier out, but that was with about 700V or so on the plate.

A plate-modulated 807 is good for about 30W carrier out.

30 watt
Yes Larry that is what I thought would be reasonable. The WS 19 uses control grid modulation. Plate voltage on the 807 is speced at 500 however in reality I find on mine it runs a bit below the 500 mark under load. The system is well controlled apparently using a special tube made just for these sets to keep every thing in check. I guess the intent was a short range communication system. I have seen original specs saying range was 30 miles and have also seen 50 miles. It was normally operated into a whip antenna Like Alex (VE2AIU) is doing and tuned with a variometer. Power rating on CW was given as high as 18 watts although 15 watts is more common. On MCW and AM or R/T as we called it normal performance is given as 3 to 5 watts. Testing using my somewhat crude perhaps but reasonably reliable method has shown that to be true. Modulation when pushed tends to be downward. Something most of are not used to however to the receiving ear it sounds quite good. A bit of fine tuning and a purpose built tuner brought output power up significantly and I am now able to get just under 7 watts. In reality I am sure I just recovered otherwise lost power by focusing it if you would allow me that expression. What I didn't expect is how effective this radio is. It is PW by anyones definition and yet i seem to be able to talk almost everywhere I could with my Dx60B even with the Amp. That surprises me. tonight I worked Dave AKA_ _ Very Weak whom I am sure you know. That is a long haul in my way of thinking on 6 to 6.5 watts out AM. He said if I remember correctly "You are Pi--Weak but audio is very good." My average distance is around 280 miles out and I have done it now several times. I have been getting 59 reports on most contacts at the range. I wonder is it because of the modulation system. It sure isn't because of the power. I don't really understand it all yet as it is a bit new. I got these radio basically because no one else wanted them and I wasn't real hot on having them but didn't want to see them destroyed. I have now found a schematic for my radio which is known as a Canadian MkII model and was specific to Canada although is not hugely different then the British sets. I find the Military schematics hard to read with the long lines and squared style so little by little I will distill it into a "Don Friendly" version. There is a modulation mod that was used in the field with a small control box that brought modulation from a max of 40% to over 100% if one spoke too loud. I have the schematic for it and may try it as it involves a pi set up of three resistors and a couple of switches. These sets have a full tank intercom also in them, sufficient for six positions and use a pair of 6v6s as intercom output. The mod involves switching the mic to intercom and dumping its output into the HF sets mic input through this attenuator resistor pi network giving the radio a quiet voice mod. Apparently it works very well. I may try it as all mods are external to the set and easily implemented. I may also try using the same intercom system rated at 48 db gain to plate modulate the transmitter in CW mode and see if that has any value. It would not take more then a few minutes to try this if I had the mod trans in hand and the guts to try it. It could also be done externally since the PA plate supply is separate and easily assessable as is Intercom input and output. As you can probably tell I got lot more radio then I bargained for. While not powerful it seems to be effective. For me I am still a bit mystified. My Dad was an expert on these radios being the instructor on their maintenance and repair during the war at No 1 Wireless School. Since I first got interested in radio and hamming he told me I should have one. I ignored that. My brothers tell me he is quite excited I now have one. I haven't seen him since I fractured my spine racing as travel was

not an option but I may try this week. It is a couple of hundred miles drive. He is now in his 92 year so he may not be interested in explaining much however my brothers say he has been talking about it quite bit so we shall see. Anyway after running this radio for a few weeks now if it was the only AM set I had I would be ok with that. Sorry for the long bla bla. Been listening to Timmy and its beginning to rub off perhaps ;>)

Hi Chris,

Here's the list of the ones I would debate:

1. Don't have it longer than 75 feet for sending out a 200-meter wave.
/(75 feet is only 0.11 wavelength at 200M and would result in a lot of ground losses. I suspect this was said because they really didn't understand matching back then and were simply trying to maximize the antenna current indication in the shack.)/

2. Don't fail to have the resistance of your aerial as small as possible. Use stranded wire.
/(The individual strands oxidize and actually have a higher RF resistance than a solid wire of the same material and diameter.)/

3. Don't operate a transmitting set without a hot-wire ammeter in the aerial.
/(The hot-wire ammeter introduced losses, and a temperature-variable resistance, similar to an indicator bulb, and should be shorted out after tune-up.)/

4. Don't use solid wire for connecting up the parts of transmitters. Use stranded or braided wire.
/(See #2. above. By the late 1920's solid buss bar wire was the standard for wiring transmitters as well as receivers.)/

5. Don't use a constant current to heat the filament, use a constant voltage.
/(Constant current would be easier on the tube when 1st applying power to a cold filament when the resistance is very low. The author may have other reasons, though, that I'm not seeing.)/

6. Don't fail to use alternating current for heating the filament where this is possible.
/(Any receiver or amplifier will always have less hum with DC on the filaments. This was listed as a "receiving don't," but the same applies to vacuum tube transmitters of the day, few as they may have been.)/

7. Don't use wire smaller than No. 14 for connecting up the various parts.
/(Also a "receiving don't." Gross overkill, and this practice wasn't found necessary later in the decade.)//

/
8. Don't try to assemble a set if you don't know the difference between a binding post and a blue print. Buy a set ready to use. /(If you follow his advice you'll never learn the difference between a binding post and a blue print!)/

9. Don't try to operate your spark coil with 110-volt alternating lighting current without connecting in an electrolytic interrupter. Don't try to operate an alternating current power transformer with 110-volt direct current without connecting in an electrolytic interrupter. /(I don't know what he means by an "electrolytic interrupter," but these two appear contradictory. From the first "don't" you might think an electrolytic interrupter is a "slop jar" rectifier, but that makes no sense in the context of the second "don't.)/

Gentlemen, Once again, I seem to lack a part for my current project. I am building an 804 PAstage for my vintage transmitter.

I need a 250 uuF (aka 250 pf) Mica capacitor. It needs to be compact, due tomechanical considerations. The old WW2 surplus type CM-55 (?) is perfect. I havea fair collection of the type but not the value needed. A minimum Working voltageof 2.5 KV is required.

I would be glad to purchase or swap for it. In a swap just let me know what valueyou would like.

I have attached a JPEG of the type I need. Let me say Thanks ahead of time fortaking the time to look.

Sounds like a good plan Larry. Alex will let us know the time here and we can be ready. Did you ever think you would be QRO man in the group with your 10W homebrew?

OK, Don, I'll keep an eye open for when Alex posts the QRG here.

I'll have both wire antennas tuned up on 40M. One is best for local, the other for DX. I'll use the one that results in the best signal, of course. I've had pretty good luck operating AM in the 5-10W range as long as the frequency is clear. If you guys can't hear me, I'll put on something with more oomph.

OK. Control- (or screen-grid) modulation will give you a maximum carrier output of 1/4 the maximum CW output, at 100% modulation. So if the maximum CW output is 18W, the maximum carrier output on AM is 4.5W (PEP output on AM is still 18W, assuming 100% positive peaks).

If you cut your power from 20W to 5W that's a 6 db decrease, which is just one S-unit. Unless you're right at the noise, the operator at the receiving end isn't going to hear much, if any, difference.

You should take the set with you and show it to him, while you still
can. I'm sure it would bring back fond memories.

I would hang on to something that will go up on 10 and 15M so that you
can talk with folks back in the "old country" on AM when conditions
allow. I was having good, solid QSOs with all sorts of European stations
on 10M AM last fall, and earlier this year, with the 10W hbrew rig.

> Sorry for the long bla bla. Been listening to Timmy and its beginning

No problem ;-) I QSO with Tim almost daily; gives me time to get some
work done at the bench!

Hi Hi, That is what I am doing when I am listening to him. Yeah Dave told me he has also been working a lot of 10m QRP lately too into Europe. I used to do a lot of 10M on SSB when I first got the phone endorsement on my Amateur license many moons ago. When I got my Advanced Amateur I sort of forgot about 10M. Now I don't have a 10M ant up although have one half built in the basement. Dx60B will do 10M. Today I finished the Cathode modded 40m 29 style rig. Haven't put fire in it but it is all done. Finished it listening to HLR. So I guess the No 19 is ok at that power out on AM and the only way to improve it is to up the total power from the 807 if one leaves it stock. IE 30 watts Cw would give approx 7.25 watts grid modded on AM. I am having good success with it so I think I will just enjoy it. I heard from Dave and he said he had no trouble copying it at all.
I see Alex has given us his sked. 8am to 10 AM EDST so we should be good to go.

11180. Electrolytic Interrupter

Yahoo group: AWAGroup (2014 — 2016)
Date: 2015-04-01 22:10:06 UTC
From: Roger Kuchera
Topic: 11180 Message: 11180

An induction coil or "spark coil" (archaically known as an inductorium or Ruhmkorff coil after Heinrich Ruhmkorff) is a type of electrical transformer used to produce high-voltage pulses from a low-voltage direct current (DC) supply.To create the flux changes necessary to induce voltage in the secondary, the direct current in the primary is repeatedly interrupted by a vibrating mechanical contact called an interrupter.

Topic: 11181 Message: 11181

I did go and vist my Dad today. I hadn't seen him in several months since I could not travel far until recently after my accident. That was 6 months ago. He is now living in a "home" and is 92 years old. It is about 170 miles away from me. He was always a big fan of the No 19 having taught its repair and maintenance during the war at No 1 Wireless School to Wireless Mechanics as they were called back then. He was always disgusted with me for not buying one when they were plentiful. It was the Russian lettering and the $19.99 price tag (my No 11 cost only $4.95) I avoided as things seemed a lot different at 14 or 15 then now. Anyway he had heard I know had a pair and one running and had been talking to my brothers about them. I wondered what he would say to me. It seemed fortunate that at 92 he even still had an interest in Radio. We discussed me having it a bit and I told him I was surprised at how well it worked for just 5 or 6 watts output on AM. His comment (yes comment) was short and sweet. "That, Don is because it is a very good radio!" I should give him his due while I am at it. He went after the war to a P-Eng career which included "Giving FM Radio Its Working Voice" (mobile commercial) for GE and designing the Radios for the famous Avro Arrow (lots on the web about this famous plane)and the Canadian version Voodoo jets (gas can radio, I think ARC552) while a design engineer for Collins Radio Company of Canada. He founded the first private EMI lab in Canada (I was a shareholder in this as the corp was mine from a previous deal) which is now part of Nemko of Norway, now the worlds largest in this field so I don't take his comments with a grain of salt. He still has an interest in this stuff which is surprising to me anyway. I guess I can hope at best I am still operating my Vintage shack and my No 19 when I am 92. Dad never desired to be a ham but did lead me in that direction early on.
I asked him about that once and he told me "You are an amateur. I am a professional."(OUCH!!!!)

Subject: [AWA Group] Mica Cap needed [1 Attachment] Gentlemen, Once again, I seem to lack a part for my current project. I am building an 804 PAstage for my vintage transmitter. I need a 250 uuF (aka 250 pf) Mica capacitor. It needs to be compact, due tomechanical considerations. The old WW2 surplus type CM-55 (?) is perfect. I havea fair collection of the type but not the value needed. A minimum Working voltageof 2.5 KV is required. I would be glad to purchase or swap for it. In a swap just let me know what valueyou would like. I have attached a JPEG of the type I need. Let me say Thanks ahead of time fortaking the time to look. CUL, Roger/K1TG

11185. electrolytic interrupters

Yahoo group: AWAGroup (2014 — 2016)

Mercury and electrolytic interrupters[edit](left) 3-electrode Wehnelt interrupter used in high power coils. (right) Mercury turbine interrupter. The motor turns the toothed wheel while a stream of mercury is sprayed on the teeth. By adjusting the wheel up and down the duty cycle of the primary current can be changed.Although modern induction coils used for educational purposes all use the vibrating arm 'hammer' type interrupter described above, these were inadequate for powering the large induction coils used in spark-gap radio transmitters andx-ray machines around the turn of the 20th century. In powerful coils the high primary current created arcs at the interrupter contacts which quickly destroyed the contacts.[1] Also, since each "break" produces a pulse of voltage from the coil, the more breaks per second the greater the power output. Hammer interrupters were not capable of interruption rates over 200 breaks per second, and the ones used on powerful coils were limited to 20 – 40 breaks per second.

Therefore much research went into improving interrupters, and improved designs were used in high power coils, with the hammer interrupters only used on small coils under 8" sparks.[5] Léon Foucault and others developed interrupters consisting of an oscillating needle dipping into and out of a container of mercury.[1] The mercury was covered with a layer of spirits which extinguished the arc quickly, causing faster switching. These were often driven by a separate electromagnet or motor,[1] which allowed the interruption rate and "dwell" time to be adjusted separately from the primary current.

The largest coils used either electrolytic or mercury turbine interrupters.[1] The electrolytic or Wehnelt interrupter, invented by Arthur Wehnelt in 1899, consisted of a shortplatinum needle anode immersed in an electrolyte of dilute sulfuric acid, with the other side of the circuit connected to a lead plate cathode.[1][6] When the primary current passed through it, hydrogen gas bubbles formed on the needle which repeatedly broke the circuit. This resulted in a primary current broken randomly at rates up to 2000 breaks per second. They were preferred for powering X-ray tubes. They produced a lot of heat, and due to the hydrogen could explode. Mercury turbine interrupters had a centrifugal pump which sprayed a stream of liquid mercury onto rotating metal contacts.[1] They could achieve interruption rates up to 10,000 breaks per second, and were the most widely used type of interrupter in commercial wireless stations.[1][6]

A bill has actually been introduced into Congress which would extend the provisions of PRB-1 to CC&R's, REQUIRING then to accommodate outdoor antennas for amateur radio operators. It is critically important that LOTS of people send letters to their representatives in support, or this bill will go nowhere. Go here: http://www.arrl.org/hr-1301 for details, but also, the ARRL is asking that we send our letters to THEM, so that: * the letter doesn't go to a place in Maryland where it takes six weeks or more to be screened for explosives, and * they have a reason to call upon the representative face to face to deliver a bunch of letters to them. In Santa Fe County, it is almost impossible to purchase a home where CC&R's don't crush ham radio. If one does find and select one of the rare pieces, it still can take YEARS to get a permit for even the most modest of antenna supports. County law is only just now getting around to complying with NM state's PRB-1. 73, Fred KT5X

Hi Don,

The band this morning was noisy, I broadcasted anyways on 7290 every 40 sec or so did you hear me?? I was keeping it short because I’m on batt pwr , but an AC psu is in the plans for the near future. What kind of psu are you using ?? I’m attaching a pic of my WS19 Mk3. I’m not using the variometer because I think its screwed up I’ll need to go inside of it and see what’s going on with it.

I was listening. Twice about 9 or so I heard distinctly my call letters and once I was sure I heard "Don". I answered but no response. Conditions were terrible with SSB interference early on and later a Kb3 plus the high noise level. I gave it my best shot and the last 15 minutes put the no 19 through my amp but to no avail.
I am on batteris also for the receiver and ht1 power and use a small bech supply I built to supply the extra for HT2 which I piggyback to the HT1 . Have you tried the No 19 and your ham station tuner on your regular ham 40m antenna? I am around all day so if you want to try agin around noon and around 4 pm I'm in.
i charge my battery with a solar panel. BTW.
don

Hi Don, we could try have another go perhaps Sunday evening or next Saturday morning I'll let you know the time.
I used my spare antenna tuner with my WS19 because my Variometer is screwed up.
So in my smalll list of things to do are make a WS19 QSO with Don , Purchase a better 12v batt from Canadian Tire
get the Variometer squared away maybe raise the ant a bit.

Hi Don. I think that may have been me. I gave you a few calls around
that time, and you came back to me. I made a short transmission and
turned it back to you, but you were gone. After that I called you
several times but heard no response.

So I went down frequency to 7285 or so and hung out with K1GUP, W1TNA
(what a callsign!), and W1BBC for about 45 minutes. I was running 10W
with my homebrew PW screen-modulated 6CD6 rig the whole time.

Well the first time I was pretty sure it was you, Larry. In fact I went back to you on that assumption. Your ID was smothered by QRM but it sounded like your voice. When you were in the clear it was fine. The second time someone was right on top of you. There was nothing wrong with your signal. I was getting QRMed severe closer in. I could not sort it out. I stayed at it though till about 10:04 my time. This afternoon the band was not good at all for me. So I worked on my 10m antenna and now have it set upon the rear deck.

Have you made any QSOs with it yet, Steve?

Is it just for 80 and 40, or will you include 160M (or even 20M?)
eventually?

Larry - I worked a few of the locals just before taking it off the bench last week. Lou gave me a 229 on 80m but it was just past sunset here and poor Lou needed his beauty sleep...ideally we should have run much later on 80m which has not been too friendly of late either. I'll wind 160 coils for it in Decemeber, between the first and second weekend. No plans for 20m unless we can move that band into BK territory...now that would be fun as we could have some daylight Transcon-fun...of course one would have to keep one hand on the rx to follow the signal up the band :-)

Hi Guys,

This past week, after an absence of several years, I hooked-up my old Radio Shack PRO-2004 scanner to the 50' tall outdoor TV antenna here, & proceeded to scan a number of what USED to be commonly-used VHF frequencies here, both Amateur AND commercial / government...

What an absolute shock to hear NOTHING at all breaking the squelch!

I am especially amazed at the profound & VERY real absence of any 2-meter repeater activity within the 50, or so, miles of my place: time was the repeater channels were just TEEMING with users lining-up to get on---but no more.

What the heck has happened...? Where'd all of the VHF users go---besides just the repeater crowd...? I KNOW the receiver works, because I am able to pick-up stations within the FM broadcast band with it, no problem whatsoever...

Is this vacancy symptomatic of EVERYWHERE, I wonder...?

I have been poking around at a 45 Hartley with a 01A cathode modulator. I got it up and going this week but wasn't happy with it initially. I made a few mods including split feeding the cathodes with a pair of resistors like I did on my TNT years ago. It liked that even on the modulator. Tunes continuous from 1850 to 7300kcs so I am good on 160M 80M and 40M. I currently have no key jack but will install one bypassing the 01a modulator as it is series cathode modulation. I had it on 40M this afternoon but no joy however it does appear to be working reasonably well. I will post pics later. (gotta steal the XYLs camera)

Here it is just after its first test. The big knob is the tuning cap (inside the wooden chassis) which comes from a 20s Harris radio. It is a big cap and has a range it would appear of at least 365 if not more (500?) The coil is from my 20s transceiver and is one of the inner ones I removed. The big tube is a 45 and the antenna (Farnstocks) is fed with a two turn loop. The circuit is a Hartley. I no longer use the movable tap. After building several I have a preference. The Hartley tube and the mod tube use separate heater supplies. It simplifies the design problems and since they are not the same voltage anyway it made sense. The lead from the cathode of the Hartley fed from the centre of the two cathode resistors which feed each side of the heater(cathode) goes to the plate of the 01A. The B- from the PS is fed into the cathode of the 01A through an identical resistor Y network. The 01A is in total control of all Bneg going to the 45 tube osc. The 01a is fed from an audio transformer through a .1 cap. It can be fed direct but works better through a cap. .1 seemed to me to work best. (I have been playing with the design for a couple of years in discrete form) I stole the bias for the carbon mic from the 01a's heater battery. I am using a #3 hand mic but am looking for a cheap busted candle stick phone to replace it so it will be period correct. I started out with a 1920s audio transformer from an old set but it didn't supply the proper ratio for the project so I subbed this one for the time being. I may try making a cover for it so it looks right or search for an early phone audio transformer which should work. I could rewind the early one I have except it is good and I can't bring myself to destroy it. I am still thinking this through. I tested it on 250 volts on the B plus. with cathode series mod you can use more as there is a fair voltage drop across the mod tube so the 45 doesn't really see the 250 volts in service. An extra 100v would be my preference.

This morning while cleaning my shack I heard Gerry K1GUP IDing . I flipped the switches and warmed up the No 19. I was able to work him fairly well considering conditions and completed a short AM QSO. That is a new DX record for me with the No 19 and more then I though possible. 417 miles ATCF. I am starting to love this old transceiver. I was as usual operating barefoot. (about 6 watts out) I would like to try it on the twin 811A amp now just for fun. I have now exceeded my goals for this rig running barefoot. Never expected it to be so much fun.

AWAGroup... I asked Don for any leads to sites covering early German ham radio history. Lou

---

Translation is a bit nonsensical, but basic info is there. Tks, Don. It appears that Ds were on the air thru the war.

"The highlight of the "research" was a double detector with a Umschaltspule. This epoch-making machine was that it did not find the authorities, installed in the toilet of Slawyk family." Odd place to hide a detector. :o)

What is a "Umschaltspule"? Does not translate.

"Um" is turn, twist, divert. "shalt" (shalter) is "switch" and "spule" is "coil"
So - tunable coil or slider coil, adjustable coil? Wrapped around a toilet?
Obviously for listening to Hitler's speeches.
bis bald,
Dan - W7OIL
PS - probably hidden in the toilet *tank.*

German or Deutsch does not translate well and rarely well word for word but will give the general jist of the conversation. For me I must think in Deutsch to function in it and that takes a bit of time usually an hour of being in it till I get comfy. If I was asked what that is referring to I would say from the general feel of the conversation it is talking about an old style wire detector.(looks a bit like a crude wire recorder) Some will know which style I am talking about.
I can probably find a drawing on my old 1917 Radio Telegraph manual.
I tried for several hours to send this to Lou on the QT by email but my email would not allow it even when went to a WIfi location so I popped it in here. My apologies for the fuss. Or as my familie Dolmetsch (Dulmage) would say over there." Es tut mir leid."

From: Roger Kuchera
Topic: 11219 Message: 11219

Gentlemen, I got the following from a German scholar friend of mine:
Ah, German compound nouns! Wonderful things. I had to go looking for that one, and then the two parts separately. I believe we would translate it as something like "backup reel." The verb form, "umschalten," means "to switch over [from one thing to another]," and "Spule" is the same as our word "spool." Online it appears mostly in electrical diagrams.

I took from the piece that this is what it was talking about or Slawyks version of it.
Re German , In 2005 I was contacted to do a race engine for Christophe Schwartz, a German National living in Verseilles France (Camtechs Corp) The whole complete conversation both business and technical was conducted in German by Email but when he came here to finalize it and bring the Start Money once the plan was agreed to I discovered he spoke perfect English. I asked him why we did it all in German and he said "Your German is different but very understandable which we find fun to read." I learned it at 50 years old so I could talk to my original family in Germany. When I read I just read and absorb. When I speak or write I give it my best shot and try not to over think it. Because I think I am German from both Mom and Dad (third largest ethnic group in Canada) there is an instinctive component that I did not expect however my direct ancestor Johan Adam Dolmetsch left Germany in 1709. Also our name means interpret. In Germany you need a Dolmetscher to translate.
Anyway enuf of that. The mag detector used a moving iron wire in two spools passing through a glass or ceramic tube wound with a coil connected to an earphone (the Old Navy book says a telephone) A pair of magnets placed with opposite poles affecting the moving wire acted on the magnetism in the wire making the signal detectable. The signal was introduced to the moving iron wire by another large winding on a spool which was connected to a tuned circuit and coupled to an antenna. Hidden in a toliet may not actually refer to one of mr Crapper's invention. This was 1920 or before. I can remember folks in the 50s and 60s still tripping outback in the moonlight to "That little ol shack outback" In fact this may have been the original Ham Shack!

I see the magnetic reel to reel wire detector is also pictured there in the UK stuff. This device is intriguing because detecting is not done live but around the corner and the rf signal carried in magnetic formation style to the detector proper. One could have wit a simple design change record their recieved signals for playback later even if that was never thought of in the moment. This device with its clockwork spring driven mechanism is the fore runner of the wore recorder and later tape recorder. There is a functional wire recorder for sale in an antique shop in the Ottawa Valley. I go there because he always has old bakelite earphones and mics etc for sale. I asked him how it worked and he said not bad although not hi fi. Then moving over to the Czech piece Lou showed us you see Czech's first amateur sitting outside with his radio in front of what looks like a "toilet" , perhaps a "two holer," The concept that clandestine Amateur Radio equipment was hidden in outhouses may not actually be so far fetched.

Spurred on by the success with my No 19 on low power I took another look at the transceiver I built several years ago. Built on a wooden chassis inside a 1920s radio cabinet it is basically built with 1930s parts all scaveneged from an old radio with some 1920s stuff thrown in for good measure. I have had it on the air and have twice in two different years made an AM contact with it. Not great but able to complete the QSO so that was ok. Now having had several good QSOs with the no 19 I want more from this one. Power wise they are not that far apart and that was the first thing I did in reviving the set after making it a new power supply. Tested to see if they were close and they are with the No 19 being about 1.5 watts more. I played around with ouput tubes running a 6l6 EH then a old vintage 6l6 black plate and finally a old 6v6. I settled on the 6v6 because it matches the modulation system the best.While the 2 6l6s will put put more power carrier wise the 6v6 modulates better being able to fit right into the desired screen voltage plus modulation that the system needs. I should explain the screen voltage on the final is adjustable from the front panel. It bugs me that the no 19 gets an answer almost everytime I use it while this set has only had two good contacts and yet power is similar. I suspect it is because the no 19 has good modulation in relation to its carrier while this set is peraps shy of that. I want to sort that out as like this set a lot. The problem is compounded by the fact that there is almost no local AM or vintage activity near me so anything I do with it is some form of almost DX. If the No 19 wasn't so effetive I wouldn't even be thinking this. So I have raised the modulation percent some, rebuilt the PA tank so it fully tunes (80m and 40M continuous) Rebuilt the power supply and played with the tube selection. I also reworked the Rx antenna inout and can now copy HAMS on AM with ease(and SSb and CW as well) The recver is a two tube regen with a 6sn7 and a 6v6 for tubes. The Tx carriers an identical set of tubes. The set tracks well and has RIT for any minor adjustments that may be required. So I will be laying with is when opportunity presents itself as well as the no 19 set. If you hear it jump in.

I was playing around checking with clipleads and discovered the Electromagnetic carbon mic circuit will feed the 6v6 screen direct.(plus dc screen voltage adjusted down for room) I didnt think it would so never tried it before. Sounded real good on a monitor rx . Better then before. Going to explore it a bit just to see where it leads. Maybe 1 tube early beam power Am transmitter. A la 1934. Did not expect this bypass to work so well. Anyway it will take some testing to see. Might just be a fluke of some kind.

"circuit" Typical for early telephones, early hearing aids etc. AKA electromechanical carbon mic circuit but both descriptions are commonly used.(and google well)
Anyway The experiment turned out for me to be interesting and worthwhile as the end result was I was able to really improve the modulation of this little hb rig. Good performance is now centered on Screen control pot about 1/2 way which is what I like on controls. I don't like having the sweet spot near the ends. This has spurred me on to experiment further with no valve or tube (kein rohre) in the speech circuit with another low power rig. Might not be practical but it will be interesting. In the end I re-installed the triode in the speech circuit but as a result of this testing was able to really improve its performance to a level that surprises myself even.

I am as most of you know very interested in early simple forms of modulation. Almost by accident while I was playing with my old transceiver project and as I mentioned tried feeding the carbon mic bias battery, audio transformer to the screen circuit direct. It worked and pretty good too. Eventually this led to a series of small mods that gave the radio a much better voice and I restored the triode amp (1/2 a 6sn7) to the circuit and now that project is back in service. However I was intriqued by this and spent all day yesterday trying different things with the old telephone style passive amp circuit. I had read you could stack three such units of the old telephone repeaters in series for more output. I tried a pair of audio transformers, the first driven by a carbon mic , bias battery (6 volt) and hooked to a normal speaker audio transformer secondary. The primary drove a second also reverse connected through a .1 cap. I measured AC voltage with a simple analog meter as it was on the bench. True the what I had read the voltage at the second transformer was almost double what I had measured with a single transformer. Next I fired up the 45 tubed TNT and inserted the primary winding of the audio transformer into the key circuit (cathode keying) and spoke into the mic. while using a monitor rx to listen. Worked pretty good. even with one transformer only. I was surprised . I had tried the urban myth with just a carbon mic plugged in before and had discovered that doesnt work so I was surprised how much amplification comes from these simple circuits. Next I took my 5016 bare essenstials transmitter and installed it permanently. Plugging in a 3736 crystal. It seemed to work very well on the bench into a dummy load. I moved the whole deal upstairs and discoved my upstairs small carbon mic did not like the circuit much however I got the one I was using downstairs , a WW11 military hand mic (Lou and I use them for loop modulation) and it worked beautifully. I gave my XYL a Grundig crank portable tuned on freq and sent her for a short walk. "The further away I got the better it sounded" she said. Today I will be trying it on air during the day. (3736kcs) I had built a two tube AM cathode modulated rig recently. Now I realize at low power(under 250 volts key down Plate V for instance) this is all I needed and a single tube would have done well. There is a lot more to this as I spent all day trying different things and won't go into it all here. This is the jist of it. For those recording mod % and audio quality with a Spectrum analyzer monitoring every wiggle looking with glee for the slightest miss-step, this is probably not for you. For those of us curious and into fun side of the hobby it may be another fun area to explore. don

Hi Lou, It was good to hear from you. The power supply I got with the UTAH Jr. was a homebrew replacement. It is of no use to me because it is very under-poweredsupplying only 260 volts, no load. I have no idea what the original power specswere. Having an original would be the berries. There is a Hammond chassis thatappears close to original dimensions. The original is only 1" high. I'm guessinga transformer that supplies 750 v.c.t. would be close to original.

I have finished the RF deck but need to build a supply and re-finish thecabinet. I had everything glass bead blasted.

I have attached a JPEGs of the RF deck. Any help would be most appreciated.

Take care and stay well.

From: Niel - W0VLZ
Topic: 130 Message: 11268

yeap, but look at the other two...three Utahs, one being the larger UAT-1 and the current one modified down to the bare steel chassis, on the block recently.(btw, take a look at http://www.radioblvd.com/1937Station.html)

Given the 30's cash crunch and relative ease of home brewing a CW transmitter I would think most built rather than buy. Given this homebrewing mindset, rebuilding a low power transmitter like to Jr into something "better" would be, unfortunately, pretty common.

Take a look at https://www.prismnet.com/~nielw/k5cf/W5GST38.htm . K5CF was my stepfather. In the late 30s he "hot rodded" his Gross CW25 with a couple of T-20s so that he could get on 10 meters. Countless SW3s were turned into preselectors.

Where's that time machine so I can go back and rescue a few of these before they fell to the Black and Decker syndrome?

73,
Niel

From: dulmagedon@...
Topic: 11270 Message: 11270

Saw two complete No 19 set ups in the Hartenstein Museum. (Arhnem) One with the rare Canadian 813 Amplifier although the main or exciting set was not Canadian. Took pics. I took a Grundig portable and did some SWLing . Listened to part of the Mil radio surpls colllectors Sunday morning net as we sailed the Zuiderzee. Ship had a lot of QRM but found a reasonable spot to listen.
Had enough cheese for a bit. Time for some more radio!

From: dulmagedon@...
Topic: 11273 Message: 11273

Yearly I make a trip to the Stirling Flea Market. While automotive in intention I have bought a lot of radios there.
Today I picked up a 1960s CB (LindsayC27) that has a complete 12 V or AC power supply. I would like to put the PS into service on my no 19 set. Cost was $10 and it is all there and probably works. The tubes are worth the price easily. I also picked up a heath vector scope Model 10 101. While intended for TV use I belieive I can press it into service as a monitor scope . It works and for $5 I wasn't going to leave it behind. My most expensive buy was a 1930s telephone for $25 which I can use for the carbon mic element and the receiver.
Because most dont know what they are selling. Other treasures over the years are SX66 RX, 59R Trio Com RX, Atwater Kent model 20 with tubes, King neutrodyne with tubes, just to name a few. Today there were two 1920s Westinghouse battery radios (1920s) but neither had tubes so I left them.

11274. Need a Pilot 391 Audio transformer

Yahoo group: AWAGroup (2014 — 2016)
Date: 2015-05-03 04:34:39 UTC
From: JAMES HANLON
Topic: 11274 Message: 11274

Folks,

I'm making this post on behalf of my friend John Anthes. John is a lot of things to me, my neighbor, a former colleague at Sandia National Labs, the President of our New Mexico Radio Collectors Club (NMRCC), an AWA member, and a dedicated collector of the things we hold dear.

John is restoring a Pilot AC Super Wasp, and he would very much like to find an original Number 391 Pilot Audio Transformer. It has a 3.5 to 1 ratio, and John thinks that the resistance of the primary may be around 670 ohms and the secondary 2930 ohms. He is willing to set up a swap for other parts or a surplus radio or to pay cash for it.

Can anyone help him find this transformer? Please correspond directly with John at jpanthes@... .

Thanks very much,

Jim Hanlon, W8KGI

Lou, do you think this is a knock-off? Look at the lettering by the power switch and then search for images of the AC-1. There are some with that ½ offset lettering but most of the pictures show the lettering either centered on the switch or cleanly offset to the left of it. Just a thought!

Hi Ron,

It's the real deal all right. As to the screening, I've looked at many of the photos on the AC-1 Group site and while there a few with the screening "sort of" centered, most were here, there and everywhere. The one offered on eBay now is just a bit worse then most. ...Still...still

Lou

Actually my wife and I are giving NJ extra points. We were on our way to Amsterdam and the tour had a "deal" on flights ($299 return .Can funds) We flew from TO to Newark on a Bombadier puddle jumper and had 4 hours stop over. During that time we got hungry and the XYL went to buy some food where she could use her Bank card because we had only Euros not US funds). She got her food and it wouldnt work with the Canadian Card. We carry a Chase Manhatten MC card as well but before she could even think about that the fellow behind her paid the bill and told her to pass it on to someone else when we got the chance. Now Jeff does this for me. Must be some nice folks there I am thinking.

Well, certainly not Newark, but my folks lived in S. Orange and my grandparents lived in Chatham. I have very fond memories of NJ, and there are still very nice parts of the state. I imagine you live in one of them. I think NJ gets an undeserved "bad rap," overall. When my kids were young we took them down to the Jersey shore, from Maine, a couple of times for vacation. We moved away when I was 5 or 6, but my grandparents lived there until I started high school.

Hanging my head in shame because I have to ask (not being a current member of AWA)...

I presume results of the BK are out. I'm wondering if scores were up or down compared to recent years. Conditions seemed horrible, yet there were plenty of stations to work which leads me to conclude there were more stations active. What's the word?

By the way I got so consumed with other things it took a while to realize I wasn't seeing group posts any more. For some reason Yahoo had stopped sending them to my email, yet it said my address had not been bouncing. Anyway, I got that sorted out!

What vendors do you use?

I have used tubedepot.com and tubesandmore.com. I know there are some that cater specifically to antique radio repair,
But can not remember the names. Please help me out.

Thank you,

Robert S Jenkins

Robert,

For capacitors and also for a wide range of modern components I often use www.mouser.com . They do indeed offer a whole lot of stuff, their paper catalog has 2190 pages, and they have no minimum order. Their prices are quite competitive.

If you're looking for modern capacitors, I get most of my parts from Mouser. Occasionally they don't have what I need or I don't like the price and I end up going to Digi-Key, Allied Electronics, or Newark.

Don, thanks for the kind words. Yes I was relentless. I didn't really intend to be, but competing is in my blood and it just takes over when I get into an event like that. I'm glad I got the chance to work you during the QSO party.

I would like to get another old time radio build done soon but I have so many other interests competing for time. I just finished doing a ham radio licensing class (it was fun but took a lot more time than I expected), I've got major repeater maintenance to do, I've been building out a computer network (LAN) spanning three locations with long range (6 mile) point to point WiFi links (partly ham related), I'm planning a major rebuild of my antenna farm, putting siding on my house, digging out stumps in a part of the antenna farm I cleared five years ago (a never ending process), etc. It will come up though. I'm thinking next winter I should finally get the '29 receiver built and if I'm very ambitious maybe that second stage of the transmitter. I may have to ask around for a part or two.

73,
Paul

It was fun for me too although I am more curious then competitive. I have become addicted to various simpler forms of AM. Wish I didn't live so far from others with similar or ANY AM equipment. Anyway keep up the good work. You have certainly captured the spirit of the era. I felt like I should dig out my old wire rimmed glasses just to work you. Suddenly it was 1929 it seemed. I have one more antenna wish here. A 160M long wire for my upstairs shack. Never been thrilled with my inverted 40 80 vee although it does function. After installing the long wire downstairs I have realized for this particular QTH it is the best by far antenna system I have ever had here so I would like one upstairs as well but east west rather then north south. I recently finished a beverage of sorts for upstairs (studio A)and it is working fairly well so I guess it is time to get the ladder out and git to it while I still can.

Topic: 11300 Message: 11300

I finished the AM transmitter today and gave it a few trys although today's conditions on 40m are terrible here. Never heard a single signal anywhere on the band which is very unusual. The transmitter is a 171A Hartley osc but its cathode or B neg voltage is controlled by a 01A in series with the feed. The 01A is controlled by a carbon mic , battery and a suitable audio transformer. It is not a big power rig but it seems to work quite well. Took a little fooling to get it to this point. It worked from the git go but modulation wasn't what I wanted at first. I also tried a 45 tube and it works but my Power Supply favours the 171A in the application better. It might reach out but it needs to be a good prop quiet day however it works so that is fine by me. I am parked on 7290kcs

I finished adding an audio stage to the one tube regen. It is now two tubes. Currently 01As. It works. So I took the bare essentials tx downstairs and gave it some much needed maintenance. I also gave it its voice using a telephone electromechanical amp to modulate the cathode.It was an accidental discovery. Might not be wonderful but it does work. I also tested the output of the BE rig now that it sports a 50c6 instead of its original 50L6. I was surprised to see it is slightly higher then the No 19 set. I would like to do another but with a VFO circuit and a tube speech amp. I have three 25l6s. Might be fun. Or to keep it 1930s I could use 6l6s. I am running out of projects. All that is left is a clone I built of the simplified T1154 circuit. I need to finish the modulator circuits. Those British Military schematics give me headaches. VFO and PA are up and running on it already. Wish the bands were in better shape!

Thought the Group might find this recent correspondence between Larry and me of interest.

73, Lou

At the bottom of this is a portion of the four page article mentioning the early development of Hi-C tanks. Part of the TNT's history that I have never come upon in any ARRL publication.

Circut form: Radio Broadcast magazine, January, 1926

Tube: 201A or 112
For interest sake, note 1926 Hi-C tank.

What is this circuit called?

Well, I would call it "Hokey" or "Rube Goldberg" or, at best, "Inelegant." [The article though is none of these. There is a lot of meat for anyone wishing to acquire a "feel" for ham radio of that period.]

It's a Hartley, but there is an unnecessary 2nd tank coli (the one on the left) in parallel with the main one (the one on the right) which seems to be there only for the purpose of coupling to the antenna. One could more easily link-couple the antenna to the main coil on the right, and totally eliminate the coil on the left, in which you'll recognize the circuit as a Hartley with the ground reference at the grid. (The ground reference is usually chosen at the cathode/filament, but could also be at the grid or plate). Of course, if you were to eliminate L in this way you would have to increase the inductance of Lp/Lg to be equal to the inductance of the original parallel combination of Lp/Lg and "L." If it were me, I'd just build a conventional Hartley with the filament at B-/ground. Much easier to manage. If you connect the plate directly to one side of the tank coil and break the DC circuit between the grid and the grid side of the tank coil with a capacitor (~0.002 - 0.005 mica) you can feed the B+ at the tap, and you won't need an RF plate choke. See, for example, George Grammer's Hartley for 160M published in 1932 QST (I forget the month).

Why the filament chokes? (It's a battery operated rig.)

Because since they chose to ground the grid for RF, there's now RF on the filament, which needs to be isolated from A+/B-/ground, or the circuit won't oscillate. That's why it's usually more convenient to select the cathode/filament as the ground point.

What does the .01 across B+ & B- do for you?

It's an RF bypass so that the B+ side of the tank coil is at RF ground, i.e., so that maximum RF voltage can be developed across the tank coil, and so that no RF appears across the B supply (unlikely that it would, anyway, since the B supply should present a low impedance to RF, but it's good practice).

73, -Larry/NE1S

If you wish to have the full article, please write to me directly.

I re-drew it this way:

I would move the .04 cap over between the plate and var cap, and continue the B-/A+ line over to ground.

What was the reason for the reluctance to ground the B- line as we see in so many of these early transmitter and receiver circuits?

Rather then A+ B- I split fed (10ohm resistors Y) my Cathode feed into both heater feeds on my AM Hartley I just finished.I reasoned rightly or wrongly it was a bit better way to do it. My TNT is done that way and it does a great job. When working with directly heated tubes sometimes you have to dance a bit to get it to do what you wish. My Hartley on this AM only rig is a conventional cathode centre tap, top grid GL, bottom B-ground.

Yep, that would be much better. That puts both rotor and stator of the
variable at DC ground, which is safer, plus the plate spacing on the
variable can be less, as it now only handles the RF voltage, whereas
originally it needed to deal with the sum of the RF + DC supply voltage.

I never noticed - I always assumed B- was grounded, regardless. AFAIK
there's no reason not to ground the B-. Maybe they omitted it because
they make the same assumption, and, as it would be common practice
(again, an assumption on my part), just forgot to draw it on the schematic?

Michael -

My understanding of the electrical code is that the Neutral wire should never be connected to
ground other than at the entrance panel.

A 'chassis' connection is no problem, until you connect an external antenna to it!

Hi Lou,
Here are a couple of pix of my effort to emulate an older type cap box. The box material is an old shirt cardboard. I added one pix of the cap mounted on my UTAH power supply (non-original).

I didn't have a decent pix of the original boxed capacitor, so I just cut it too fit the Sprague Atom that I wanted to use (20 uF @ 600 V.). I used 2-part Epoxy to stick the cap to the box and Elmer's for the box flaps.

As for the chassis, it is not an original but the closest thing that Hammond had to offer in a steel chassis. The original dimensions were 11x6.5x1". The one I used is Hammond part 1441-15BK3. It measures 10x6x1". I guess trying to squeeze a transformer on the chassis under the RF chassis shelf required a bit of smoke and mirrors. BTW: The new chassis is short in width for the sheet metal screws they used to tie the chassis to the cabinet. The two switches can be used to hold it in place.

I made a series of improvements; solid-state rectifiers, regulated screen voltage, fuse and 3-wire AC cord. Overall, it should be more efficient and not generate as much heat as a vacuum tube rectifier. I forgot to mention that I included a switch on the rear apron to set the screen voltage either hi (200 V.) or lo (100 V.), the lower voltage can be used for tuning up.

I gave the supply a no-load smoke & flame test yesterday and it passed with flying colors. The B plus came out at 440 volts but under load will have to wait.

The most difficult part of the restoration has to be done. The crackle finish paint job.

I have heard that the original Jr.'s had a weakness in the power supply area. I've heard from several guys that they or some previous owner had to replace the transformer. I have a feeling UTAH went shy on the filter cap.

I was working on two of my other simple transmitters and tried something with a carbon mic , battery and audio transformer. Much to my surprise I could make it modulate with just the mic and electromechanical amplifier. So after finishing the AM Hartley and the reworking of the transceiver project screen modulator I took the Bare essential rig downstars and installed the electro mechancial amp in the cathode circuit. It worked but needed some rubbing. Today I worked on it some more and while not perfect it has stepped up a couple of notches and is doing the job. I haven't had a on air QSo yet and conditions are not great for Low power 80m rigs at the moment but I am trying it when time permits on 3665 kc. It tune a but low closer to 3664kcs but in monitor rxs even some distance away appears to be working. The BE rig is a simple crystal controlled 50C6 transmitter with a transformerless supply. I am hoping this proves practical. An old electromechancial telephone repeater would be even better but they are pretty scarce these days. Anyway like all experiments in ancient technology it has been most interesting.

I am gathering the final needed parts for the next project.

I am looking for a Weston RF meter:

Model #425
Range, 0-1Amp
Metal case
Face dia., 2 1/4"
Flush mount

I consider any condition worth discussing as long it has been proven to be working.

Like this, but the RF mtr. version, Model 425.

Will buy or trade for this 1920s Jewell RF meter below in very good condition, 100% working order.

Thank you.

73, Lou
VE3AWA
Ldvermond@sympatico.ca

There is minor paint chipping along the flange edge. There are mounting screw head scratches around the mounting holes.
The photo does not show that the scale face is "fresh" with the early production crystalline silver surface.
Total face dia., 2 3/4"

Gentlemen, I am on a quest for two (2) Hammarlund Ceramic (Isolantite) coil forms. I need the five (5) pinvariety. I believe the Hammarlund part number is CF-5. I would prefer they have the woodenpull handles but that is not essential. Used or unused is fine, as long as they are useable.

I have one (1) 6-pin form of the same type and short version that is roughly 1/3 the size ofthe CF-5. I would be gladly trade for them or let me know what is a good trade. I would also beglad to pay for them.

Thank you for your time and effort.

Roger/K1TG

11315. 1943 ARRL Radio Amateur's Handbook

This is Victoria Day Weekend in Canada aka Firecracker Day when I was a kid. Every year in Picton at the Crystal Palace at the old fairgrounds they have a Antique Show. I always take the XYL because I believe it is good to keep her happy. Occasionally I find something. Today I was there about 10 minutes and found hardcover edition of the 1943 ARRL Radio Amateur's Handbook. I didn't know the ARRL books came in hardcover. I thought only the"other" radio handbooks came that way as I have a 1940s version of one of them. Anyway a bit of dickering (I have been watching Down East Dickering and am getting better at it) and I had it for $20. Lots of interesting projects using tubes that were popular in the 30s and 40s. Funny that while I have some 1940s and 50s handbooks I see no repeats in this one. Now where is my stash of 6l6s. (BTW he also had a very old booklet called The Psychology of Morse Telgraphy but I couldn't bring myself to pay $25 for it.)

The first transmitter project in the book is a Breadboard Transmitter and begins by saying "go to the hardware store and buy a breadboard (5 cents) and four rubber feet." It is a 6L6 (optional 6v6) crystal controlled design from I would guess 1934. the receiver section has for its first project a very good regen design expandable in the second chapter to a Simple Superhet and the regen becomes a fixed regenerative detector and a mixer osc is added. Might be a fun station to build and operate. Power supplies and antenna tuners are included for each project. In the PS for the transmitter for a 6v6 use choke input PS and for 6l6 move the choke for capacitor input filter giving 300 or 450 volts respectively. A lot of the projects are very buildable and are an expansion of the previous at least in design which is a great way to learn and progress. There is even a simple 200 watt two tube CW transmitter. Now I know this isn't pre 1929 stuff but it is interesting and very buildable just the same. I am not sorry I bought the book.

Hi Don,
Your comments served to spark my memory of a high school library book, whose contents included an expandable, "learn as you go" radio transmitter. Stand alone freq multiplier stages and PA stages were described, that could be added to the basic transmitter (xtal oscillator?).
IIRC, a 20 or 25 watt (plate dissipation) triode, whose type number I've forgotten, was used for most or perhaps all of the transmitter stages, that were described. My financial status insured that I could
only drool over the subject material!
I regret that I do not remember the title, of that most interesting book.

I have part of a 1942 Handbook , now the 1943, a 1948 and a 1956 plus the "Other" handbook 1940 vintage. I used to have a Harrmalund 1934 Shortwave Manual but it has vanished somehow. I think I will build the breadboard just for fun. I Lou still has his we can do a breadboard QSO if the bands come back to life. 80m or 40m, Lou?I have everything but the 2.5 RF chokes. I should buy about 50 of them because I am always scrambling looking for subs or making workable ones. The HRO is in there on page 19 but it isn't a No7. It says to see the 1942 book for # 500 HRO rack model. Only the Table HRO and HRO jr are listed here. The picture though is a rack mount.

Building and putting on the air those one tube crystal controlled rigs is a lot of fun. I've built several and have used some of them in the AWA Linc Cundall Old Time CW QSO Party.

A few years ago I went so far as to build up an early 50s Novice Pair. See https://www.prismnet.com/~nielw/1951NoviceStation/1951station.htm By then a lot of the simple rigs were built up on "slat board" chassis. If you had an old orange crate you could even save money over that breadboard.

73,
Niel

I have two orange crate rigs. A TPTG I used in the BK as well as its mate a Hartley. Both 01As. Worked Paul with both. I used the Morroco tangerine crates as produced that we get at the local grocery store. The only Rock bound HB tube rig I have is my Bare Essentials 50l6 rig which is now a 50c6 rig for a bit more squeak. It does a decent job and recently became an AMer as well by way of series cathode modulation. (Still one tube)
I would like to do the Breadboard Transmitter as close to the one in the book as physically possible. BTW where is everyone? Band 40M was open but no one around today. Surely not everyone is mowing their lawn!

I appear to have all the parts "in stock"
As an aside have also been working on a 40M Am three tube transmitter I am calling Triple Threat. It has a 12ax7 osc buffer, 6bl7 speech amp/mod and a 829B parallel pair final. The Osc is slug tuned. It is just a something to poke around at project but is sort of building itself. Triple Threat because it is a miniature, an octal and an semi-exotic tube. And all tubes are double tubes in single envelope.

lest someone should think I was kidding here is the one I made starting with a standard Bliley crystal. I cast the adjustable body in my home foundry , machined it on my mini lathe and installed a tension bolt and spring. Because the crystal frequency varies with the tension appllied to it one can vary the frequency quite a bit relatively speaking. Much more then you could with trying to rubber it with a capacitor. It was all duely recorded here when I made it a few years back and it still mworks quite well. However it isnt very pretty and it isnt original. Whether that is how Bliley did it I don't know but I discovered the effect while regrinding and testing my own crystals for my rock bound rigs. don

The adjustment knobs on the VF-1 and VF-2 crack rather easily from over-tightening the set screw.The knobs are nearly impossible to find and replace.

Breadboard drilled, test assembled, sanded, varnished and drying. Many parts soldered to tube socket and crystal and coil socket. Maybe tomorrow for the smoke test. Will let it dry overnite. Also found a 7145 crystal I didn't know I had . It isnt a round Bliley but I planned to make a plug in adapter anyway. So that would give me 80m and 40M if I want to wind the coils (or install a shorting switch to cut the 80M in half)

Hi Don,

How are you going to get 80M from a 7145 XTAL? Or did you mean with an existing 80M or 160M XTAL that you may have mentioned in a previous post?

40M and 20M (14.290, close to 14.286 - 20M AM calling freq.) no problem with the 7145 XTAL.

73,
-Larry/NE1S

Previously I had no 40m crystals only 80M so I had not considered going on 40M or winding a coil for 40M. However now I have a 7145 crystal I found in my junk drawer. It is an old CR/8U. I hadn't made provision for that style crystal as I have lots of 80M Bliley rounds. So I would have to build an adapter to plug that style into the other socket and wind a coil to match it.Or I could centre tap the 80 meter coil as it is a 4 pin deal and just throw the switch on the 80m coil cutting it effectively in half giving me 40M but I would still have to change the crystal. That was a given I thought. Anyway the varnish dried and the rig is now about 80% wired. XYL is on a bus trip tomorrow with WI so I may have time to wind the coil on the plug in form and fire it up. HF bands however are currently crap here. don

3736, 3561, 3500(too close for comfort) I forget what my adjustable is but it is in the 80M Cw portion. I also found a adapter I had started to make years ago so I will finish it. My other rock bound tube rig the BE has sockets for all three common type crystals so that is probably why I didnt finish making the adapter deal. I have others in my junk drawer but they may not have been good spots. We can of course also operate split if you don't have matches. I used to op quite a bit of split DX back in the 80s. I will check the adjustable in the morning and see what it is. I didn't write it on it anywhere.
Some may wonder why I wouldn't just double for 40M from the 80M crystal. Two reasons. One there is a note in the article that says that is not recomended for this rig. Why I dont know but also you loose some punch when you do when you only have one single stage tube or transistor.
Anyway it is about done so I will holler when ready but the band will have to improve. Today I could not hear CHU even on the beverage. And even W1AW CP was just a wisp now and then and not copyable in any way shape or form.

I was listening on the high end of 40M late morning yesterday and the
signals I did hear were extremely weak (WA1HLR talking with W2IMX). I
called a couple of CQ's with 80W from the Viking I on 7290 and 7295 but
raised no one.

I was also listening there 7290. I could just tell someone was there and that was it. Once in awhile a couple of words then it completely closed down and just noise. I fired upone of my single tube AMers and gave it a half hearted shot just in case but it was a wash no matter what. Adjustable crystal goes from 3633 to 3634 plus a bit.

It works. A bit light on power perhaps as power supply drops to 246V under load but sounds good and works so as soon as we have a decent condition day we shall give er! I only had to fudge two values. My cathode resistor is 400 ohms instead of 200 ohms and I used a .005 shunt instead of a .001 in the top side tank to plate. My coil form as 1 1/4 inches instead of 1 1/2 as mentioned in the article but that was a minor thing to deal with and it now tunes to the crystal nicely. I used a 2 turn link out. I guess my chokes are of unknown value but appear to be working fine.

Subject: [AWA Group] Meter trade or buy

I am gathering the final needed parts for the next project.

I am looking for a Weston RF meter:

Model #425

Range, 0-1Amp

Metal case

Face dia., 2 1/4"

Flush mount

I consider any condition worth discussing as long it has been proven to be working.

Like this, but the RF mtr. version, Model 425.

Will buy or trade for this 1920s Jewell RF meter below in very good condition, 100% working order.

Thank you.

73, Lou

VE3AWA

Ldvermond@...

There is minor paint chipping along the flange edge. There are mounting screw head scratches around the mounting holes.

The photo does not show that the scale face is "fresh" with the early production crystalline silver surface.

Total face dia., 2 3/4"

Mike, Lou: An ignorant question: do those meters have the thermocouple unit built in, or does one need to find one of those in addition to the meter proper?

But what does the scale mean? "current squared"? What units? How does
this translate to power/watts?

GE Mike and All,

Thank you for remembering my want. At 100ma. that would be considerably less than what is required.

GN, Lou

45 min.s to go on the TNT. Bids seem low considering what it is. Hope someone here will have a new old rig for the Kelley.

Easy to add a shunt if you are just using the meter to indicate relative power and not absolute power.
I have the meter you need and will trade it for a silver-faced Weston 425 with a full scale rating of 1.5A or 2A.

In that case my meter will not be suitable. It has a brown micalex? back instead of the 1920s authentic black bakelite back. I ruined a 425 once trying to exchange a brown back for a black back. Not one of my proudest moments.

The bands have been dead here lately. I have had zero air time as far as QSO go since I returned from the trip. Some No 19 and No 9 (angry 9 I think) guys wanted to try a pond hop between NL and USA last night so I tuned in to see of I could hear. I didn't hear them but was shocked at the amount of activity around 7025 to 7045. I checked 80M and it was a dead as a mackeral but i suspect no one there rather then the band itself. Apparently the Pond hop was a succcess. I dont know what an angry 9 has for power but I do know the 19 on CW can reach 19 watts if one is lucky. Anyway if you can't sleep it is something to try. I checked on at about 2200 hrs EDT. Meanwhile back at the ranch I had my new breadboard on my 1929 tx s supply. That supply has adjustable DC filament voltage so I decided to see what it actually had. 4.72 volts. It really smartened up when I gave it 6.27v. Pays to check.

Hi Lou

I finally got time to go through my meter stash. I do not have exactly what you want, and am not sure if you can adapt something else. I have attached a photo of the RF ammeters I have. The two on the right have built in thermocouples (according to the guy I got them from), and the one on the left has an external thermocouple. All are untested and a little ratty, but should clean up.

Will any of these work?

Dave

Here is the finished transmitter. It appears to be performing well but hasn't had a QSO yet. The band was wide open this morning around 730 to 8 local time but no one was on (80M) I always check the time signals with my portable. This morning CHU was S9 even with the antenna folded down! Last week I could often not hear it no matter what. I remember back in the day when I was a teenager wondering why anyone would build a time signal only receiver. finally a few years back I got it. Best way to check the band openings especially 80m and 40m . CHU east west, WWV north south for me.

The attached are from the Feb.,1922 issue of, Wireless World, the "Official Organ of the RSGB".

The article features the UK winners of QST's Second Transatlantic Test where Canadian and US hams transmitted while English amateurs/SWLers listened. The station with the most calls logged wins first place honours along with wireless instruments.

Below tells the story of the second place winner, H.H. Whitfield. This post is for the hopelessly romantic O.T. HBers among us...

Afternoon all,
I have an SW-3 that I would like to try and find out what its approximate year of manufacture and version is. It has a 36 for rf amp and detector and a 37 (has 237 engraved on the wafer socket) as the audio amp. It has a four wire cord and a B+ switch on a long shaft in the left rear corner. It does not have the voltage divider resistor. It is working nicely....except for scratchy pots that need cleaning and maybe needs calibrating. I have the 40m BS coils (13A) and have been tuning around on 40 this PM. I will go thru it and re-solder the solder joints, clean pots, ck resistors, etc. Since its working so well, I am gonna assume (yeah, I know what it means) that the caps & resis. are close enuf, but will ck a few anyway. I am using a string of 9V batts for about 125vdc, under load and 6.3 vac on fils. with no hum noticed. I've had it for a number of years, but got the bug to play with it some more after recently acquiring the 80m BS coils. Would it have originally used the balloon type tubes? Ones in it now are the 'coke bottle' shape. Is there anything else I could look for that would help with the dating?
Anyone have any ideas?

Thanks, 73 de Bill K4JYS

Hi Bill, Over the years I have owned 4 of the little beauties. I believe that the earliest are referredto as Type 1. The lift for the lid is flat with no indentation for a your thumb/finger on the Type1. I don't recall the tube compliment.
  Big hint: The ground lugs are riveted and can present ratty grounding after all these years.Clean them up as best as you can and try and sweat them to the chassis with a hefty iron.
Make sure the posts where the grid clips go (when using the BS coils) are clean and notpainted.
  Once you get the hang of them the SW-3 is a delightful radio.
Roger/K1TG

Bill,

From your description of the tubes and the coils, it looks like you have a Model I SW-3. This was the first version that came out in 1931 and was built as far as I can tell until 1933 or 1934 - or perhaps until 1936 if you believe Bill Orr. The main Model I version intended for AC power used a 35/35/27 tube lineup, all with 2.5 volt filaments. There was a variant intended for 6 volt DC filament power, probably in mobile service, that used a 36/36/37 lineup, and a dry-battery version with 1.4 volt tubes using a 30/30/32 lineup. All of the Model I radios used the 10 and 20 series coils. The Model I SW-3s are pretty scarce.

The Model II came out in 1933, 34, or 36 depending upon whom you believe. It used either 58/58/27 tubes with 2.5 volt filaments or 6D6, 6D6, 76 tubes with 6.3 volt filaments. The coils for this model are numbered from 60 to 72. Most of the SW-3s you find these days are Model IIs.

The Model III came out in 1941. It used either a 6J7G/6J7G/6C5G lineup or a 1N5G/1N5G/1A5G tube lineup. Coils were numbered from 30 to 42. Relatively few Model IIIs were made, and they are also scarce.

A couple of articles you might enjoy are, "The Year is 1931. National Radio introduces the SW-3 All-Wave Receiver," by William I. Orr, W6SAI, CQ, July 1971, pages 34 to 38, 94, 96; "The National SW-3 or, The Quintessential Regenerative Receiver," by Jim Hanlon, W8KGI, Electric Radio Magazine #52, August 1993, pages 10 to 14, 33. I can scan copies of these articles for you and a copy of the SW-3 manual if you send me your email address to w8kgi@... .

I'm sure you will enjoy your SW-3. 73,

Jim Hanlon, W8KGI

To all hands: Please note that the Antenna and Oscillator nameplates are reversed!! The oscillator tuning shouldbe on the left and antenna tuning on the right. The pilot light jewel is non-standard.

I was down testing on 3561kcs with the 43 rig nd getting nowhere. Just to my right is my homebrew twin 811A amp so I decided to try the 43 on the amp. No issues, They like each other. A simple switch to 80 meter settings, a quick tune on the light bulb dummy and I was in business. Looks like around 60 watts approx.
Works nicely on it but still no joy.

GA all,
Here is an update on my SW-3. Thanks for the comments and esp. to Jim,.
W8KGI, for the specific info I was looking. Going by the tube lineup in the
rcvr I have, looks like it is an early version....possibly as early as 1931. There
are a few other identifiers that are a bit different than the early model, but
I think the tube lineup in this one pretty much nails it down to the above
date/area. I have been playing with it on 40m (had 13A BS coils on hand)
and its a hoot to use. This morning I made my first 40m QSO using the SW-3
and it worked just fine. As usual with regens, it does have a few quirks, but
I will get used to them with use. Yesterday, I received the 80m BS coils
(64A) and plugged them in this morning. They seem to work ok, at least I
am copying a few 80m SSB stns and our TV switching P/S noise. I will try
it out on 80m CW later this evening. Hopefully I won't have to do any coil
trimming on the 64A coils. The RF gain pot (LH side) works very nicely.
I have been putting the 'Readability' adjustment around the middle of the range.
I am using a pretty long antenna, so sigs can be very strong and some overloading
will occur. An adjustment of one, two or all three of the controls will reduce that
problem.
At least with this SW-3, varying the controls will move the frequency around some.
Oh, when I took the back cover off the RF gain pot to clean it, I was intrigued
by its construction. Internally, on the outside rim of the pot is the resistance element,
next
toward the inside, is a springy type shinny metal ring which is pressed up against the
resistance element by a little insulated plunger which is attached to the shaft and
goes around the ID of the metal ring, pressing it against the resistance element
as the shaft is rotated....neat design and probably cuts out the possible sparking...
and noise, you might get during adjustment of pots with the wiper directly on the element.

To Don: You are right, the Utah and SW-3 would make a great combo...wish I could
afford that Utah...bet it will go for a big price.

Back to regening....73 de Bill K4JYS

11388. Special day special deal, more NO 19 stuff.

Today was a special day for me.It was at 1;20 AM this morning I officially qualified for Canada's "Cash for Life" program aka pension plan. I often wondered of I would actually make it so woke up and had a hot chocolate by myself to remeber the exact moment. Today she took me to the Ontario Regiment Tank Museum right beside the Oshawa Airport on the old WWII military base.. I didnt even know it existed till she saw a sign while returning on a bus trip. Today was Tank Day complete with a reenactment commemorating the battle for Arquino by the Canadians in may of 43 I believe. The tank Fury with which some will be familiar with from the movie resides here and was rolling around firing its guns along with several other military vehicles. Since my No 19 Wireless set is a tank radio used by the Canadians and clearly so identified I was hoping there would be a signals display. There were several no 19s on display in their appropriate vehicles as well as in the museum proper. I had taken my Hamfest VE3LYX clip on ID and popped it in place just in case. Go idea I met VA3HFB and VE3SIN at the signals display and had a great time chatting and trying some early CW field gear. Was asked about participating sometime with my No 19. I would be ok with that. In the flea market I met VE3SMF who had a bunch of later style noise cancelling mics for sale. Then I wandered outside. At the second table on the ground in a standard Ammo box I saw a couple of real honest to goodness No 19 mics complete with cords and plugs. There was other stuff in there as well. I called the vendor over nd mde a deal to buy the whole box on the spot. I paid more then I wanted but siting here now I have three complete proper no 19 WS microphones one of which also has the big original earphones and cabling .A set of NOS earphone pads for the above (no 19s do not use a carbon mic but a moving coil mic so these things are now difficult to find and I have been making do to date.) Two mics like the WWII carbon ones Lou and I use for "you know what". One with its cable and plug and one without. A spare parts box makes No 19 in WWII stencil but empty. A complete jeep dynomotor cabling and jones style two prong plug (I have a Dynamotor that will fit this.) Three 12 pin PSU dogbones. A B set VHF antenna in rough condition. A switching block of some kind with wiring and of course the big old Ammo box besides. I think I will keep the earphone and mic assembly and one of the hand carbon mics as well and flog the rest for gold to help finance my radio addiction. I had given up ever finding the dogbones or a real proper No 19 mic. Been a good birthday thanks to a great XYL.

Hi Bill, Quirks! :) :) Welcome to the wonderful world of SW-3s. Mine will hear anything that the multi-buckrice burner, I have, will.

Sometimes, the later coils (so-called Universal Model) need a extra turn or two to work with theolder SW-3s. The later model used higher gain tubes thus need fewer tickler turns.

I'm still trying to figure how to get the coupling link on my UTAH Jr. to give me decent loading. Iwired my Antenna cap in series with the link for low-Z output. Yes, indeed that would be first-classcombination.

Hi Roger,
So far have only had experience with two regens, the SW-3 and the one tuber
from 1935 RADIO using the '19 tube. I was pleasantly surprised at how
sensitive they were. I believe my SW-3 may be one of the early versions and
am using the 64A coils for 80m which worked just fine. Am using the 13A set
for 40m. Good luck with the Utah and look forward to hearing that nice station
on the air....73 de Bill K4JYS

My sentiments are similar to Roger's " Mine will hear anything that the multi-buck rice burner, I have, will."
Despite what you might think I NEVER felt using the regen was a handicap when operating. I always knew I could hear more and could sort it out usually from the different pitch. It required far less antenna so I could use a Rx only antenna eliminating relays switching etc etc. I have currently 7 regens operational. I am sure your SW3 s that is both of you are more the up to the job of a QSO , SSB, AM or CW.

Just when I thought I was done with commercially built stuff other then WW2 military radios I have been bitten by the "I need an old Shortwave regen bug." In my minds eye there is one I saw pic of as a kid that had a long central plastic pointer and was a regen. might have been a lafeyette or a knight kit but I have been thinking of it all day as I worked on the no 19 (fixing and installing the extras I bought Saturday at Tank Day) I could do a clone. I have a vernier like the National SW series although the dial is a bit rough.I am thinking. The DX60B and it matching receiver have to leave the shack so I am selling them. A small commercially made regen would fit right in. I have a Starr , pre 1920 but it is for broadcast band. I also thought of breadboarding one to match my 6l6 breadboard transmitter .Probably with a 6C8. Anyway look what you started Bill!
don
(I told someone recently I had 7 regens already . I lied . Actually 8)

Yes!!! The marine RAL receiver makes the SW-3 look like a toy, in the same way the SW-3 makes just about all other regens look like toys. (My experience; YMMV).

Of course, the RAL (and it's low frequency sister the RAK) is Navy WWII vintage, so, considerably newer, and, substantially larger and heavier than the SW-3. There are also some RCA Radiomarine regens from the mid 30's that are excellent, along with a few MacKay Radio Marine, like the model 128 WWII regen.

Has anyone used a better HF regen than the SW-3 ? Homebrew or commercial?

bob...w2ami x wn2ami 1962

Yes!!! The marine RAL receiver makes the SW-3 look like a toy, in the same way the SW-3 makes just about all other regens look like toys. (My experience; YMMV).

Thanks Garey, I have been a member there for many years.
My all time favourite regen is the 6sn7 twinplex. My least favourite is the Powerhouse Receiver. Most fun build was the POW Radio built literally from garbage from the local dump including a thrown out thought to be defective I guess 56 tube and a busted 1/2 of an earphone set.You can hear it on You tube running for the first time using garbage dump batteries for power. I have built several Hartley based regens and several of Armstrongs (tickler coil) as well. As well as my VLF regen which I forgot to count. I am very curious about the SW-3 circuit . Anyone have schematic? When I was just into my teens I built 12ax7 one that was a good performer and in my late twenties rebuilt a version of it which I gave to my niece. Both the original and the replacement worked well but that is too new a tube for us here. I have never built a colpitts regen.
I have a twin 01A Armstrong running today beside my 6l6 1943 transmitter. It is my own design as are many I have or have had. I started on the breadboard regen today . Sockets are mounted , coil forms are located. May have to buy the variable caps as I don't have any single gang ones left unused. While I don't have a 6c8g tube as per the 1943 ARRL book I will use a 6sn7 most likely. That requires no circuit changes. This is good discipline for me to build by the book as I usually free build with no schematic or article. Tis good to tow the mark now and then. Make no mistake. I love regens! Even built them with no variable tuning cap. I like pot regen control but good pots are hard to find so I have built them with throttle caps as well. Which method does the Sw-3 use?

Don -

OK, I guess I coulda' looked at the member list first!!!!

I've attached a couple of docs re the SW-3. I have lots more. I have 1-1/2 SW-3s, and I love
them. They are everything you hear about SW-3s!

Regeneration is controlled by adjusting the Screen voltage of the Detector, not throttle cap.

I was always a fan of the Twinplex until I got an SW-3... :-)

I think the real keys are nothing secret, VERY rigid construction, and excellent shielding make
the difference. My Model II is the complete one, and it is fantastic. I have a Model I, but the attenuator pot is broken, and a couple of other fairly minor problems. It's packed away from the move, but 'someday'.

There are some good videos on You Tube of the SW-3 in action.

If you would like more information, lemme know, I have lots more.

Thanks Garey. Quite an exotic regen. I used screen regen control in my VLF (twin 6v6) regen. It is a lot easier on the pot and is smooth. I was looking at the schematic and realized I have everything including the tubes (2.5 volters) and the front vernier dial. If I had Lou's skills as a craftsmen I would make a clone. I also appreciate the post. Thanks. Maybe I could trade my green AM station for one somewhere. (DX60B HR10B) since I no longer use it.

It's my understanding that the RAL is a 1936 design (by Hazeltine), and
the SW-3 is 1931, so the RAL is 5 years newer. Also, the markets they
were designed to satisfy were completely different, and the customers
for the RAL had deeper pockets than most of those for the SW-3.

From Dave, WA8DOF's QRZ.COM bio.

I am also a proud member of the Mighty MidWest Glow Worms and try to check into the MWGW Net on 3563 at 8:00 AM (Central time)Saturday mornings. If you are a CW operator and appreciate "vintage sounding" gear, please join us.

Hi Dave,

How many of the group operate power oscillator rigs such as your Hartley?

Also, what is propagation like at that time of the day?

73, Lou
VE3AWA

Dave's Reply:

You never know what rigs will show up on any given Saturday. Harold (KB0ROB) and Russ (W0CWU) generally run Hartley oscillators in a MOPA configuration, (usually 80 to 100 watts) with a variety of tubes. Harold has been known to use a 211, an 810, an 801A, a type 10, and several military tubes whose "VT" number escapes me at the moment. Most of the guys put their Hartleys and TNT s away for the summer, and use something with a little more power.

Mark (KI0DB) has run everything from an acorn tube to an 811 in his Hartley oscillator.

Most net members are AWA members and participate in the BK and other AWA events, so all of us like to hear a little chirp now and then. In fact, some of the signals sound down right shameful! Just the way we like it!

There will also be some Heath, Johnson, EICO, Drake, Home brew, surplus military gear, Harvey Wells, and even a rice box or two. I have been running Mr. Ugly lately (see photo below). (Mr Ugly is a junk box special, built on a piece of plywood and using whatever I could scrounge up. He runs about 50 watts out.)

Several of us also use Regen receivers.

Propagation is generally good between me (Michigan UP) and Wisconsin and Minnesota, although it gets a little tougher in the summer. In the winter months, many of us get along fine with 10 to 30 watts, and some guys check in with their Hartleys at less than 10 watts. I do the NCS thing on the 4 th Saturday, and have always been able to hear everyone. We have one member in South Dakota, and he is a little tough (for me) to copy at times, but he generally runs about 30 watts.

If you are around the shack some Saturday (9:00 AM our time) why not join us? We are a friendly bunch and always glad to have new members. Attendance is a little down during the busy summer months (in fact I will miss the net next Saturday due to family events), but

should pick up later.

Hope to CU there.

Tnx Lou for the refs. I had not seen the first one you listed.
I have been using the '1929' version since around 2000 when I
made my first AWA-BK rig, the TNT. The off ctr fed hertz was the
recommended antenna for that TNT. Mine is cut for 80m and I use
it also on 40 and a few times on 20. I went pretty much by the charts
and never have tried the various ways of checking for the swr values.
The Frank Jones Antenna Handbook also has a page or so devoted to
this antenna. I guess it works...over the yrs have worked W6 on 80,
VE7 on 80 & 40 and a few other 7s during various BK events. I
even strung one up for 160m (at 30ft high) to use with the Meissner.
I made contacts with it but the coax fed inv. L sure works better.

I use an end fed 1/2 wave (on 80M) No cp . It is however the most effective antenna I have had at this QTH for 40m or 80m.I have a 80M 40M inverted VEE but it just works and that is about all one can say for it. Could just be my geography or something. On 20M I use a real Marconi (1/4 wave vertical directly over a ground rod fed with rg58.) It is also very effective even for DXing. I see a lot of theories a reasons and simulations however I now go with what actually works. I moved here in 86 and brought my tower and A3 beam here and installed it. It had been a great antenna ten lots down the same street but I never made a QSo with it here no once ever. I sold it to a contestor of some note and he was happy. I used an inverted l for sometime with decent results but from the second I put the 1/2 wave endfed single wire in the trees it has been a boon to this station. I have even moved it twice when the tree cracked and when it came down once but it still does a good job. A Ham over on Big Island has a Windom up and I have been meaning to go over and have a look. Why thisQTH is so difficult I dont know. could be soil conditions or something. I was effectively out of the hobby till I dealt with it. So wire antenna stuff is of great interest to me. Simpler the better. At the old QTH I did have a HB phased array 10M vertical system working for a few years. That was fun but I was much younger and more ambitious.
On my bucket list though I have a 40M Marconi written down. I think it would be interesting to try.

When you turn on the filaments of this beauty....it lights up the room! It looks like somethingfrom an old Buck Rogers movie. You remember (?) with Dr. Zarkoff and Ming the Merciless.

I have a similar tube circuit here for a 140 watt Amplifier. My XYL who I think I will keep (45th ann yesterday) Asked me this morning about a book I had lost and was going to look for it. It was Lindsay Publications Twinplex Rx book and it had vanished. With in minutes she found it AND my long lost Hammarrlund Shortwave Manual 1939 which I haven't seen since probably the1980s. My Dad gave it to me as he had bought it in his youth just before he went off to join the RCAF in 39. He had kept it all those years and gave it to me about 1964. The second last project in the book is a 140 Watt Amp using a 808 triode. It is a pretty straight forward deal and is built breadboard style (no front panel open controls) although appears to be on a metal chassis. The 808 also has the top and side connections. On the following pages are two PSUs one for the Amp and one for the transmitters in the book which are all 6l6G based. The big PSU uses two ballon 866 tubes and the Transmitter uses an 83 . Both PSUs are on wood and would look good in any of our shacks.
don
She also found a reprint of How to Build A Neutrodyne (1924 was date originally published) and Technical Instructions for Wireless Telegraphists published in Sept 1915 which she found at a Libray disposal sale several years ago along with a copy of The Boys First Book of Radio and Electronics (Morgan's book). She just stuck her head in the shck and grinned saying "Its pretty quiet in here!"

After reading the new revised privacy policies for EBay and PayPal after the July 7th cutoff, I cancelled my membership in both! I suppose I'll miss out on some good stuff but they want to get even more annoying...

Just me!

Ron –

I have not read it. Can you synopsize and let us know what is so bad about the new policy? I have been on there since 1997 and made close to 10,000 transactions, with very few problems. 73 – Mike

I have only read the “Changes” as put forth in the pdf in a link that appeared at the top of the logon screen. I got rid of my home phone when it degenerated to the point that all I ever received were autodialed and prerecorded messages.

****
Section 1.10
We are updating terms of the PayPal User Agreement regarding the means through and purposes for which we may contact you.

The revised section 1.10 reads as follows:

1.10 Calls to You; Mobile Telephone Numbers. You consent to receive autodialed or prerecorded calls and text messages from PayPal at any telephone number that you have provided us or that we have otherwise obtained. We may place such calls or texts to (i) notify you regarding your account; (ii) troubleshoot problems with your account (iii) resolve a dispute; (iv) collect a debt; (v) poll your opinions through surveys or questionnaires, (vii) contact you with offers and promotions; or (viii) as otherwise necessary to service your account or enforce this User Agreement, our policies, applicable law, or any other agreement we may have with you. The ways in which you provide us a telephone number include, but are not limited to, providing a telephone number at Account opening, adding a telephone number to your Account at a later time, providing it to one of our employees, or by contacting us from that phone number. If a telephone number provided to us is a mobile telephone number, you consent to receive SMS or text messages at that number. We won’t share your phone number with third parties for their purposes without your consent, but may share your phone numbers with our Affiliates or with our service providers, such as billing or collections companies, who we have contracted with to assist us in pursuing our rights or performing our obligations under this User Agreement, our policies, applicable law, or any other agreement we may have with you. You agree these service providers may also contact you using autodialed or prerecorded calls and text messages, as authorized by us to carry out the purposes we have identified above, and not for their own purposes. Standard telephone minute and text charges may apply if we contact you.

That policy evidently caused quite a stir - unsurprisingly.

PayPal this week caused an uproar when it rolled out an updated user agreement that added a clause that allowed the company to pester users with robocalls and text messages – not only to the number they provided PayPal, but also to other numbers PayPal is able to obtain. While PayPal at times may need to call or text you regarding account activity or to settle disputes, the new agreement also broadly gave the company the ability to send out surveys, offers and promotions through automated means. What's worse is that there was no opt-out mechanism provided for these actions. But now there will be, the company tells us.

According to a company spokesperson, "PayPal customers can opt-out of receiving auto-dialed or pre-recorded calls."

GM,

I an in contact with Chris, SP6GNJ. He is building a TNT using a 201A. He has collected parts that are as per the original TNT, but still needs that 20 ohm Pilot c.t. filament resister. Anyone here with an extra? Chris is a "serous" builder....

73, Lou

11433. Heater control

Yahoo group: AWAGroup (2014 — 2016)

From: dulmagedon@...
Topic: 11433 Message: 11433

While perhaps not exact I have been using a car heater control switch for my filament control. Up here in The great White North Canadian Tire sells them in their automotive switch section. They are unchanged since as long as there have been heaters in cars and have that at least 1930s look. Whats more is they say heater on them and handle the load easily. They are not cheap being around $16. And while not perhaps the proper rheostat from a 1920s radio I would be willing to bet they were used for that long long before I thought of it.
I would think NAPA has them as well.

Meanwhile, fired up the breadboard regen today. No smoke which is always good. Throttle cap was bad (insulator cracked) but I was able to at least try it. Now to find a replacement 100 PF trimmer in GOOD condition. Finished wiring it. Not bad hum wise. Not a good day on 80M but i could find some signals so I suspect it will do the job.

don

11434. Heater control & RX comes TX

Tks Don, but Chris wants to use parts as per the original TNT. We've all been there...

Chris also wants to build a Reinhartz RX. He has only secondary info on it so I looked thru QST and found three primary articles. When reading the first article I noticed this and thought of you....

Anyone here build a Reinhartz?

I finished the rx today. Found a work around for the cracked throttle cap that works and look right as well. Spent about an hour rubbing on it trying it out. Found a minor wiring error and corrected it and am happy to report this thing is gonna need a volume control. Is it ever loud on strong stations! I was using WWCR as a reference station and it is quite strong but truthfully it was hurting my ears. For an antenna I had 6 feet of hookup wire drapped over the shack curtain rod. I can control it (volume) also by adjusting the antenna trimmer to loose coupling. Until some 80M ham activity returns to 80m I will leave it be for now. Anyway it appears to work quite well. I am even a bit impressed. However regens are tricky little devils so I will try it for a few days before giving it a grade.

Other than the sub of a 6sl7 for the 6c8 I dropped the Grid leak resistor to ground which is a normal alternative anyway should one want to use the set at higher frequencies someday. It seems to work good copying AM stations but I haven't had any CW to copy since I lit it. No activity on 80m , not even W1AW CP so the band must be sleeping.

The 6SN7 would be an electrically equivalent sub for the 6C8, which is
medium-mu. But if the high-mu 6SL7 is working well, don't mess with success!

From: Larry Woodworth
Topic: 11446 Message: 11446

We have a model 175-A Neutroceiver cabinet- serial # 50933. It is. In reasonably good condition with no other parts.

I manage Ensor Park & Museum in Olathe, Ks. We believe this item may have been donated some years ago. It is a bit surplus to our focus of ham gear and belongings of Marshall H. Ensor, who we celebrate for his history in ham radio.

I will post photos if permitted. I need to learn the procedure if someone will give the info on that. Offers of purchase will be considered.

Thanks to all,

Best regards,

Larry Woodworth W0HXS

Hello,

As you see, there is no variable condenser across the plate coil.

Also, the circuit derived its name from the fact that the grid coils winding direction was opposite to that of the plate coil. Finally, the grid coil was "telescoped" into the ground end of that coil.

How was the transmitted frequency of this rig determined?

73, Lou
VE3AWA

Topic: 11447 Message: 11448

Kind of looks like a reversed TNT, with the plate coil taking on the same function as the grid coil in the TNT while the grid tuning determines the frequency...just a guess at first look.

In the twinplex it makes little difference if I use a 6sl7 or a 6sn7 however in the cathode modulator it makes a huge difference with the 6sl7 out performing all others that will sub so I choose it for this and stole it right out of the modulator sitting in front of my ARC5 TX. If I remember correctly I think an' N7 has a 20 amp factor and an 'L7 a 70 amp factor. That was the good news. Now for the other stuff. The RX works pretty well has very strong volume and really shines on AM signals. Cw signals though are very tricky and it took me awhile to get good at it. I am not happy with its performance there and am grading it a C-. It is useable for sure and I like that it belongs with the Tx I built but I think a newcomer to regens would have hard time with it. It requires a big antenna too. (I used a ten meter one I had that was not occupied tonight but tried it on all execpt the beverage. The trimmer cap coupling does not work well for the antenna . I jury rigged a two turn loop on the coil and solved some of the ills immediately. So it is functional but not really user friendly. The twinplex though, using the same tube will run rings around it and requires far less antenna. So will my design the slugabsorb but it is solid state. I would be half tempted to build it as a tube type to see how it stacks up but in reality the twinplex is the best rx I own and will out perform any of the rest including modern ones and do it on ten inch loop sitting in the window. Am I sorry I built this one? No. I love the look of it beside it mate the breadboard tx and it does work. Would I recommend it as a regen build ? No.

My guess: With the coils closely coupled as they are, the mutual L of both coils appears across the tuning C. It looks like it would function like the 'unity-coupled' oscillator. W7OIL built the Double-M version a few years ago with the grid coil inside the tubing of the plate coil. He would surely have some insights regarding the tuning behavior.

Somethings I know from playing around. The larger coil physically or highest Q will be the dominant control regardless of where it is in the circuit with in reason. If you have played around Homebrewing some will already have seen that. Another example is with even our rice boxes of the hybrid type like my KNWD TS830S I can operate a fairly large slice of the band without retuning the final every time with very little effect on output. My TPTG is contolled freq wise also by the grid coil and the plate coil needs to be only "in the wIndow" to allow it to operate. So if the grid coil is of very good design and large enough and the seemingly untuned plate coil is tuned in the window even though it doesn't have a tuning cap but using induction and natural capacity between turns then the grid coil can control the freq and the signal will get out. On my HB linear I dont need to retune say going from 7285 to 7295. I could and could gain a few watts but I dont have to to complete a QSO and the gain would be so minor it would only be satisfying my ego rather then moving someones S meter. Keep in mind that some vintage HF sets used fixed caps in the output circuit rather then a load cap.
Here I call it the dominant Q factor. Probably a misnomer but I don't care. I understand it and it works which is all that matters in this shack. The circuit is an easy one to build. you could have it bench running by noon easily. I would use my GDO to proof the coils and tank. I think you would find it works nicely and the comparison to a TNT in reverse is very astute I think. Tuning range would be similar.

You can post it as an attachment here on this list. Just please try to keep the file size reasonable by making the image size and resolution no larger than necessary.

I could be wrong, but I don't think the demand for an item such as this is very high, and I think the cost of shipping may exceed its value, unless you find someone who needs it to replace a damaged or missing cabinet for a set that was originally their Granny's.

You may also try the AWA list operated by Ron Lawrence, W4RON. From my observations there are more broadcast set collectors on that list than here.

Hello guys, As Lou stated, I built the unity-coupled, PP 45s, SEO from the 1933 ARRL Handbook (pgs. 91,92).Feeding the wire through the Copper tubing can be a trial!!! As I went about the process, I used somewords I hadn't used since my days in Uncle Sam's Canoe Club.

I will gladly provide, schematics, text and digi pix of my project. I haven't done a great deal oftesting with it but it oscillates easily. Initial testing reveals it is prone to hand capacity. Building thisthing has to be a labor of love.

Hi Ron,

EBay has gotten so very big that its arrogance has evidently usurped any remnant of intelligence that that outfit may once have had...

You would think, at least, that the legal arm of the firm would have tempered this excess---but I guess the place must be rampant with "attitude," from top, to bottom.

I used to buy & sell a LOT on eBay---but then I came to hate the way they forced users into using Paypal, changed their rating scheme, tried to manoeuvre policy on users, raised rates, would re-vamp the way you sold things on the site on a maddening regular schedule & seemingly without logical reason, etc. etc.

The golden eggs being laid out of the goose just couldn't come fast enough---so that greedy outfit effectively killed it in their stupidity, IMHO.

Oh well, as they say, "...all things must pass." Even the once-vaunted General Motors ended-up facing bankruptcy in 2008. Hooda thunk it, right...? What goes around, comes around...

I have been testing the regen and its mate the Bb transmitter later in the evenings after Lou told me I was trying at the wrong time of day. 80M comes alive propagation wise about 10PM my time. I check time signals to find out and tonight they were almost overpowering. There has been activity right on my freq that last few nights. I should get some more rocks I guess. I only have three that work in this TX. Mostly I am using my 3561kc crystal. It sure is fun running a late 1930s style station. Especially running a Receiver built on a bread board. I am getting much better at running now that we(me and the regen) are getting to know each other. Certainly is usable station. I popped a 6v6 in the TX tonight so both TX&RX would look matched. It is a quirk I have I guess. XYL says it is ethnically based. (alles in ordnung!) Whatever I liked the look better and the TX suffered no loss of output showing on the FS meter so should be good. I don't really have a big enough PS voltage wise to appreciate a good 6l6 anyway. Input by the way is a mere 6.766 watts.

A quick email and an opportunity put Lou and I on 80m this morning with me on my loaf or breadboard station. Conditions were not great but useable .I had the HR10B on the beverage ant on back up to make sure I could hear so it wasn't the perfect test however it was a ball using a 1930searly 40s station on air. I won't be happy till I can shut the back up rx off and run only the regen and the TX but it would need to be better conditions then this morning. However you should know I have been copying the QMN net most nights as I get used to this style (throttle cap, transformer coupled) regen. I hope to try again in good conditions . I was just thinking Lou and I have had several interesting adventures. He is always up for an experimental QSO. We are about 180 miles apart ATCF. I was very pleased he could copy my 6v6 transmitter as I had feared running it on the same supply as the RX was too low HV to be useable. I had swapped out the 6l6 for the 6v6 as the voltage was closer to its happy spot. Seemed to work. We didnt push our luck as the noise level was high and signals not real strong but it was ok. Thanks again Lou. Fun stuff! Now its time for breakfast!

GA All,
This is a bit of a nit-picky question, but got to wondering just when the white beehives came into use. Were they around in the 1920s along with the brown ones or did they come about in the 1930s. Just nodding and wondering on a lazy, hot southern afternoon....73 de Bill K4JYS

Hi Bill,

In the past I've wondered that as well. Never came to an absolute answer, but safe to say that a project dated 1937 and up would be "safe".

73, Lou

Looks good. Look at the regen gridleak. It is adjustable in a fashion in relation to the cathode resistor. I also like the light colored CW key lower and to the right.

I would like to say hello to the honorable group!
It's time to welcome - my name is Chris and callsign SP6GNJ.
For over two years, I read carefully all messages in this forum.
Thanks to Lou VE3AWA - I joined a group and now I'm finishing the construction of a replica of my TNT 1929.

In response to the subject of the post - Lou I will try to translate and make for more details.

In short:

It is a replica of the transmitter and receiver where Tadeusz Heftman (TPAX later SP3AX) established the first confirmed QSL card connected with another country (Dutch N0PM station) and it was 06-December-1925.
This date was considered a symbolic birthday of Polish amateur radio.
In April 1926 TPAX established the first QSO with USA : U1AAO - confirmed QSL card .
Then try to find scans of these cards.

This replica was built by Thomas SP5CCC in 1995.

Curiosity regarding the legality of the operation of amateur stations in some European countries at that time.
(Translation of the attached portion of the scan)

"On the 1st Nationwide Exhibition of Radio in 1926, in Warsaw, radios construction Ludomira Danielewicza TPAV and his brother Leonard were awarded a gold medal. There are no regulations governing Amateur Radio activity resulted in the confiscation of equipment Award" ...Hi

That's all for now.

Vy 73! Chris SP6GNJ

PS.
Please forgive me of my poor English.

From: dulmagedon@...
Topic: 11481 Message: 11481

I have been playing with the breadboard rig quite a bit now. The difference from just built and running to where I am happy is sometimes long. the set had too much volume brought on I believe anyway by the fact that it runs on the same voltage as the transmitter. Since it doesn't control the Dc plate voltage to limit useable feed back but uses a throttle cap it can still run full plate voltage. (I may have said this wrong but ya'all know what I mean.) While it was fun to beabl hook an audio transformer to it and a speaker even with no PA audio stage it wasn't real practical to my way of thinking. Also CW tuning was tricky. So i popped a 15k resistor in the B plus feed for the regen (only) ad i added a 56pf cap parraleled with the 100pf grid leak cap. It seemed to like it. volume is still strong but below pain threshold now with phones on. It picks up CW easier now. How did I decide on 56pfs? There was one sitting on my desk in front of me so I tried it. I remembered playing a lot with the twinplex many ears ago and I found a sweet spot and have been very pleased with that radio ever since.
I will continue to rub on the combo as I see fit. Tis still a fun station though.

Sri Mike for the delayed reply. Summer and all... Trade a 202 for one of those rifles? :0)

73, Lou

Hello, Lou

Thanks for your interest. I have enclosed a photo of them - ..... they were not quite ready for the B-K last year. Should make this year, though. The old one [an orignal] is ready for 40 meters but needs a grid coil for 80 and the new one needs its grid coil adjusted.

In the background of the pic you can see my other hobbies: I build and restore cedar canvas canoes and build historical replica firearms for historical reenacting. All the radio stuff is behind me!

I do follow the group on the net.

73, Mike/WA8RVD

GM Lou,

I hope this finds you well. I forgot to mention that I became a "great-grandfather" a week ago. My oldest
grandson and his SO had a baby boy; Logan Jon. He reported aboard at 6 lbs. 11 oz. and answered muster.

I still have a little work to do on my UTAH to dress-up the 80 meter coil. I haven't put it on the air, as yet.
The output is about 16/17 watts into 50-Ohm dummy load. Now I have to find a place for it on the vintage
side of the shack.

CUL, Roger/K1TG

Lou

You are welcome to post the pictures, I only ask that you mention two things:

1. I received much help and encouragement from Harold, KB0ROB
2. I am a member of the Midwest Glow Worms

Harold has done so much to encourage people to build 1929 rigs here in the Midwest!
[emphases mine]

These are of my Hartley Osc, it uses a Type 10 Tube. Harold, KB0ROB helped me with plans and advice. B+ is 218 Volts from a gas-tube (2 VR-105's) regulated power supply

.... here is my 211 PA - I run about 200-500 volts B+, and can get as much as 40W out if I wish... Most of the time, I run about 20W out - for the contest, I run 10W input... I do run it through an auto tuner, and hopefully that holds the harmonics down!

I also use 10 VDC for the 211 filament, less hum modulation that way! I use a .0004 HV mica cap for coupling from the Osc, and get a real nice note from that combo.

For both the Hartley Osc, and the PA, I have coils for 160, 80, and 40. I run straight-through, no doubling... The large disk-type neutralizing cap on the PA helps to get the neutralization just right!

The Hartley is my main work of art, but the PA is somewhat of a prototype yet. I am quite happy with how they both perform on the air.

Best 73, Dave WB9WHG

The activities of the Midwest Glow Worms interest me. Can't find them online BTW.
The 211 rig in particular caught my attention as I built one and it was my biggest failure to date. All through in testing at around 300 v it worked fine. Then I upped it to around 700v key down an with in seconds it was running itself, no cathode B- and I think smoked its own tube. I have since found out it is recommended these tubes run a good smooth DC heater supply as the AC can be too much excitement for them. Doesn't matter now , it was all over in a matter for seconds before I could even reach for the switch to kill the B+. Heater is still good in the tube ad nothing rattles but it appears to be done! I see a very healthy neutrulizer in Dave's pics.
Maybe someday I will take a good look at his schematic and see where I may have gone wrong. For now my wallet is still hurting from losing the tube..I am still smarting from that one!

Hi Don,
You didn't explain what the "done" symptoms were. Zero plate current??
I have read that a severe overload can cause a loss of cathode emission, in a thoriated tungsten type xmitting tube, such as a 211.
Any old hb contains the info required to (hopefully) restore normal emission.

rig in particular caught my attention as I built one and it
was my biggest failure to date. All through in testing at
around 300 v it worked fine. Then I upped it to around 700v
key down an with in seconds it was running itself, no
cathode B- and I think smoked its own tube. I have since
found out it is recommended these tubes run a good smooth DC
heater supply as the AC can be too much excitement for them.
Doesn't matter now , it was all over in a matter for
seconds before I could even reach for the switch to kill the
B+. Heater is still good in the tube ad nothing rattles but
it appears to be done! I see a very healthy neutrulizer in
Dave's pics.
Maybe someday I will take a
good look at his schematic and see where I may have gone
wrong. For now my wallet is still hurting from losing the
tube..I am still smarting from that one!

Good question. The dang thing scared me when it ran away. So later I tried it at the test voltage I had been successful at a got nothing I figued it was smoked. I had wondered about sending it back to the Tube store for a test. But then i thought if it was no good I would need to replace it and i didn't really want to. The project did not suit me. I dont mind the 45s or 171As etc or even the 6l6s but big tubes like that I think are out of my serious range of interest. So when it got close to the BK weekend this year I liberated the tuning cap from this rig and used it with its matching one in my TPTG 01A rig. I didn't do a lot of testing , just confirmed it wasn't working and quit. The XYL had bought me the tube for Christmas and doesn't know of this disaster and I ain't a gonna tell her her gift lasted less time then a cheap fireworks. Still it bugs me to be beat since it was working fine a light voltage. However your guess could be correct. I hadn't thought if that. Seems to me to reactivate they run them over voltage just the heater for period of time "Boiling" the coating so to speak. If i get another ancient cap i may reassemble it and at least just keep it to hold up as a bad example.
BTW for those who like to operate. 80m has been open a ot evenings and mornings but no oralmost no Cw activity. I check the time signal to see before operating and the last coule of days it has been extremely strong here. A couple of weeks ago it often could not be heard. For instance right now it is a moderate signal. This morning before 9 AM here it was VERY strong.

In my warped and distorted mind I keep looking at my new 6l6 crystal controlled transmitter and thinking it would be so easy to sub the crystal with a grid coil and open the grid choke and have a self controlled osc. A TNT if you will. I am fighting the urge to try it at the moment but it may be a losing battle!

Also, listmember Jon AB9ZG built a beautiful replica of a 1929
Heising-modulated MOPA, in which the master oscillator could easily be
switched from an LC-tuned Hartley to XTAL control. My friend Bruce owns
it now, and I can vouch that it runs great both ways, as I've done so.

This is getting tempting. Personally I hate being rockbound especially when I know LCs can be quite good if done right.
Anyway today I am on a different project. I need a better PSU for my No 19. Something that can deliver a solid 600 volts to the final but feed the HT1 275 volts besides. Since the ARC5s use basically the same voltages it will also replace my ARC5 supply. I am today trying to decide if I will go solid state rectifiers or run a 5U4 of which I have several. I bought a new Hammond transformer (I am on Cash For Life now! Old Age Security Pension so I had to celebrate that extra income somehow) with enough 5 volt winding amps(4) to comfortably run a 5U4. It also has a rating of 288 mils for the 600 volt winding so it should be able to steady itself running either of those. The ARC5 guys like a resistor network for the lower transmitter voltages. Me I am not sure yet. I am just hoping to be able to hold at at least 580v under load on the PAs when done and I would like a quiet supply , minimal hum. Even got a 10 hnry choke with 3000 v insulated value. My brother got me a 1/2 dozen metesr on Ebay so we may even get fancy. Then the current AC supply for the No 19 will get to run the 6L6 TX. Tested it today on it and its is OK. Nothing got hot and no smoke.

Nope.

The one I was referring to uses a 210 MO, 210 PA, 250 modulator. I searched my files for photos but i don't have any, and couldn't find any with a Google search either. Perhaps Jon will see this and post an image or two.

That was my first ham transmitter. It is shown under 1928 style ham transmitter in my project gallery. I got the idea for an oscillator that is switchable between crystal and Hartley came from the April 1929 QST article on phone transmitters.There also were several oscillators shown in QST that were mentioned to be used in both TNT and crystal mode.
My second far simpler transmitter shown by Lou is still in the prototype form. I need to fix a parasitic issue before I build it in the final form. When the coil ground clip is in the position which gives greatest efficiency, the oscillator breaks into UHF parasitics when keyed. When the ground clip is advanced one turn toward the center of the coil, the tube draws more current for the same output but keys without sign of parasitics. I suspect the longer lead lengths required for the front panel-mounted tubes are forming tanks resonant at some UHF that is still low enough for the tube to oscillate at. Side view.

Hello Don,
I think your idea of a 6L6 TNT is a nifty one indeed, but the transmitter might be more stable and easy to control if you used a lower mu tube like a ordinary triode (210,250,2A3,6B4G etc).
Besides, you won't have the need for a dropping resistor or whatver you choose for the screen supply.

I'm sure you could use a 6L6 or similar tube but due to it's relatively hi mu it may be a bit squirrelky, especially on the higher bands like 40M etc.

Whatever you decide I wish you the best of luck with it.

Mod-U-Later,
Joe Cro N3IBX

First Jon D . Very nice! Most impressive!
Joe, I have got a 6l6 transmitter I built I guess around Christmas. I built it to test a couple of different ways of modulating it, satisfied my curiosity and have been robbing parts from it now and then. I was looking at it today. The PS is on board, it has a tube shield installed and the tube is still wired to go. I stole its two variable caps and both its coils. It was a TPTG and so could have quickly become a TNT. It had no issues as far as stability goes so whatever I did it must have been Ok. I have several 29 style rigs thanks to Lou's dragging me into the selfcontrolled osc world. So I am not hungry to build any more for now. I already have a TNT 45, a TPTG 201A, a Hartley 201A or 45 depending on my mood, a 171A Hartley series cathode modulated by a 201A. That is just the pre 29 stuff. XYL asked about a month ago "How many transmitters do you actually have?" (18 and about 75% homemade) It is kinda 1930s/40 style stuff here now. South of us the Crystal control thing kinda took over although it was not the hard rule up here however it became most common. We don't didn't have a Novice class. I was just looking at the circuit of the 6l6 Tx I just built and thought man that isn't much different except for the rock. That is what started the idea rather then I didn't already have a TNT. Today I was working on the new power supply(for the tank radio). I whimped out and went solid state on the rectifiers. The new electrolytics are so small it is hard to image they actually will work!
I don't like the look of them.

I have some ARC5 stuff and my WS19 sets. The ARC 5s I use on a homebrew junkbox built PSU. It works but is a bit rough to put the WS19 on. It has a load voltage of 770v B+ but since I use the ARC5 with series cathode modulation I lose the modulator tubes B requirements in the mix and with up with net voltages of in the high 500s on the plates of the 1625s. Also the lower HV for the rest of the ARC 5s is at the scream end of limits. I must confess I wasn't as concerned as I should be since both those radios were bought for $17 US funds. However the WS19 is a bit of a classic up here being a specific Canadian model (MKII Can) and being almost an NOS rig I could not bring myself to put it on the big brute. So I have been using it on a vibrator supply I have for portable tube radio use and supplying the extra HV for the 807 final piggy back with a small bench supply. It worked fine but was UGLY! so I built a proper voltage supply from what I had around. It worked BUT its transformer was unable to hold steady when I put it in Tx and so output has dropped and so has my QSO count. Finally I took some of my first pension cheque and ordered a new Hammond transformer and everything I would need to build a supply. The transformer supplies 600 volts and is rated at 288 mils so is a far cry from the pipsqueak I have on it now. However the company I buy from supplied very new style capacitors. They look like 10 ufds 25 volters used to but are rated at 10UFD , 450 volts (yes I know to series them and bridge them for equal flow) and 105 degrees. It bothers me they are so small. I am told by many they will be fine so now here I am just a fuse and a power cord needed before the smoke test. I am a bit nervous however... The older light supply is going to get to run the new 6L6 breadboard rig. Voltages should be just right for CW work and that rig doesnt need much in the way of current.
Anxious in Ameliasburgh

Don - where you *might* run into a problem is if your filter is capacitor input (vs. choke input or resonant) the peak current through the capacitor on the rectifier side of the filter choke may exceed the newer capacitors' rating, heat it up and explode it. Been there, done that. Some of the smaller, modern electrolytics aren't designed for that service. You may be OK, though. Tread cautiously and make sure the capacitors aren't getting hot.

73,
-Larry/NE1S

OK Larry, I went and got my safety glasses just in case. When I did the Linear which runs an average voltage of around 1440 v using a doubler they were much smaller then i am used to but not as small as these. I guess I will stand back , wear my safety glasses and see what happens. I may reoder elsewhere later just to ease my mind. Yes. It is Cap input. I have lots of NOS can type but I hate the thought of having to replace them. I have used a few over the years but have run across a few that were no good. Too much age I guess. And rearange everything to make room. These I can go with some bigger Spragues (My personal preference) from someone else and just clip the leads and pop them in.

Very well; best to play it safe.

If I have the room I like to use the large oil capacitors (PCB or not) that are 8 or 10uF at 600 or 1000V in this type of service. They seem to last forever.

Earlier this year I started using resonant filters where in the past I would have used choke-input. I really like them because you can have a very light "standby" load on the supply without the filter thinking it's cap input and the voltage soaring as a result.

73,
-Larry/NE1S

I read some of this story. There are some significant comments here and there that indicate Wallace had a handle on this rather then was a surprised experimenter.
As for his "design was stolen" one has to be careful. Years ago I developed a tool for use in the machine shop race engine trade. I went to the Carlise show with a basket of them. It was a severely simple solution to a nagging problem. I had field tested it with two other shops for over a year and none of us had had the problem it solved again. I was asking $5 a piece and had a bristol board display showing it all. Never even had a nibble the three days we were there. Was beginning to pack up when a fellow stopped by. He asked about it and did I design it. I told him I did and he asked did I patent it or at least copyright it. I said no and asked about copyrighting it as as an author I knew about copyrights but not as it relates to inventions. He explained he was a tool designer for the automotive industry and did tool design as a living and copyright was one option he used for short run, low cost tools. He bought one as we spoke and I said , and I quote, " No I didn't patent it or copyright it. If you think you can make a buck off it go right ahead. Be my guest. I can't even give them away !" (marketing is not one of my skills!) About a year later the tool appeared in a major companies catalogue and has remained there ever since. I saw one and borrowed a set of verniers to compare. Even the dimensions were exact to my originals which I still have. I could be mad however I did say what I said. A man stands by his word. I am sure things like this happen to many who develop things. Often the personality that invents is not a student of How to Win Friends and Influence People but an expert for some unknown reason in how to Tick Folks Off. So when I see "design was stolen" I know more about that then I want to.
Anyway it is an interesting design and I enjoyed looking into it. Thanks for posting it.

I have been running it full tilt for the last hour. Very quiet on RX. Voltages in range, nothing getting warm HOWEVER,
I have to have DC heater voltage to run the relay and the meter low voltage scale. To get the 12 volts (ca) I combined the 5v rectifier heater winding and the 6.3 winding. I got 12.75v AC But when I put a diode in series I only get 5 volts DC. I think I know what I have to do to get 12v (rectifiy both before combining.) however I must confess I hadn't anticipated that. Tis a rare day when you don't learn something.

Hi Don,

Use a full-wave bridge across the series-ed windings instead of a single diode (which is half-wave rectifier). That'll give you 1.4X the total RMS transformer voltage with a capacitor-input filter, minus an amount which depends on the load on the supply. If the voltage is too high under load, knock it down with a 7812 regulator chip and a npn power transistor connected as a "pass" device (emitter follower).

With a half-wave rectifier, the integrated (DC) voltage is less because you've only got half the waveform to work with.

73,
-Larry/NE1S

I whipped up a bridge from my junk box. It is working but I am about a volt light underload some of which is because I am at the end of a rural feed on an old green transformer that has been patched several times and I am around 113 volts most of the time. I can pull about another 1/2 volt I think by getting creative. I am going to have to filter some as I can hear it in the monitor on transmit. Anyway it works , Volume is excellent on receive and RF out on transmit is up almost 20% . Nothing is getting hot and no funny smells so this is good.
That was a very interesting deal BTW. I took the opportunity to poke around the circuit just for fun to see what where and why before installing the bridge. I will order a "real" one with a better rating. These are 3 amp diodes and I know I am pushing them even though they are not complaining yet. Some kind of a SSB contest on this afternoon even in the "AM Window" I offered them the chance to log a vintage AM station but alas no takers. No sense of adventure I guess.
don
BTW on ebay right now a photo of Montreal RCAF Electronics School (No 1 Wireless group I believe is the technical name) Middle row 4th from the right with a bit of a grin I believe is my Dad. I wasn't around then but have a photo of him about 2 years later in uniform in my living room. Looks like a match to me. He was an instructor there for most of the war. I saved it and will ask him on my next visit.

I found in my junk box three very serious 20 volt 12000uf dual section caps. I just finished installing one in the PSU using only one section and tested it with all A set heaters on. 14.73 volts which is well within normal charging voltages for automotive 12 volt applications. Depending on manufacturers 13.8v (chrysler)to 15.2 v(ford) is what one normlly sees when servicing these systems. Virtually anything in the 14 volt range would work well without trouble. Since these radios are designed for vehicle use I am assuming they have to be happy with the same.

To those interested, it's Maritime Radio Historical Society Night of Nights time again. Newsletter 51 gives all the details. KPH, KFS, KSM, WLO & KLB will be active. May be the last time USCG stations will participate. K6KPH & W4WLO will be active. The coastal stations will operate on numerous old ship/shore CW channels including around 500kc . Also great info on antique receivers the MHRS has recently received:
RCA SSB R-3, IP-501A, RAZ-1, AR-8510.
The restoration of these receivers and other info makes very interesting reading.

> 1925 Radiomarine IP-501-A receiver obtained by MRHS - and more!

> Frank Geisel's Report No. 3 for June/July 1946

> Antenna Report

Clearly we have a lot to cover in this issue. But before we dive in we'd like to solicit your support for our activities like Night of Nights and the ongoing maintenance and repair of the transmit and receive stations and their associated antenna fields. As many True Believers know, we suffered significant damage to our antenna field in a December storm. This included the felling of a 100ft antenna pole which took out the MF antenna and three antennas (including the MF Marconi T).

Downed pole in Bolinas antenna field

Since then Roy Henrichs of the Transmitter and Operations Departments has done a thorough survey of every antenna at the transmit and receive site, so we know where we stand. The picture is daunting. Everything from the guy anchors to the poles themselves is in need of repair or replacement. But now we are ready to start reversing years of deferred maintenance. To do this we figure we'll just about deplete our bank account, money that's there only because True Believers have contributed very generously to the MRHS. Can you assist with a contribution? Any donation you can make will be very deeply appreciated and will go directly to support our efforts. Just click on the button below.

Thanks,

MRHS

Make a Donation

> Night of Nights 2015!

It's that time of year again. Time to honor all those ops who came before us by preserving their skills, traditions and culture through on the air operations.

Why 12 July? Long time True Believers know the story. But it may be worth repeating for new arrivals and to remind everyone of the traditions we hope to keep alive.

On 12 July 1999 some very tough looking grizzled old radio pioneers had tears in their eyes as the last commercial Morse code radiogram was sent. It was the end of an era. And as the last beeps faded away into the static they witnessed the end of the career to which they had devoted their lives.

Paul Zell sends the last commercial Morse messages at KFS/KPH - or so it was thought

These men - and some women - had stood watch over the airwaves on shore and at sea. Theirs was mostly the business of maritime commerce. But when their ship was in peril they were called upon to send the most electrifying three letters in radio, S O S , knowing that all

their fellow radio operators would press their earphones close to get every scrap of information and bring aid to their stricken ship.

Once, our coasts were dotted with great Morse code radio stations, all communicating with ships at sea. They're all gone now... all except one, the one they called the Wireless Giant of the Pacific, located at Point Reyes.

On that sad day in 1999 another event took place. The Maritime Radio Historical Society (MRHS) was formed. We made it our life's work to honor the men and women of wireless by restoring that wireless giant. One year and one minute later the giant's voice once again spanned the oceas as we picked up the thread and kept the faith with our colleagues of the air.

Every year since, in an event that became known as the Night of Nights, Morse code station KPH has returned to the air, joined by KFS and the station of the MRHS, KSM.

This year our friends and colleagues at USCG station NMC have labored mightily to bring that storied call sign back to life on Morse code for the evening along with NMQ in Cambria, CA..

And station NMW in Astoria, OR will be on the air as well.

Stations WLO and KLB will join us again as hey have in years past.

This is a global and local event. Hundreds of listeners around the world will be waiting with their earphones on, waiting for the signals of the great station to once again arc over the dome of the Earth to their receivers.

You can be with us in person!

Dozens of people will join us at the RCA receiving station in the Point Reyes National Seashore to watch as the signals are transmitted by hand using vintage telegraph keys.

A guest operating position will be available so bring your key and 'phones or use ours and operate K6KPH. No license required! So if you're an ex-commercial op who never became a ham here's your chance to sling some Morse again. Or if you hold a current commercial radiotelegraph ticket you can operate KPH, KFS and/or KSM and have your license endorse to that effect.

This year we will have our custom made endorsement stamp available to add that special touch to your ticket.

Chief Operator Richard Dillman at Position 1

Date: Friday 12 July 2015 Pacific Daylight Time

Location: RCA receiving station, 17400 Sir Francis Drake Blvd., Point Reyes National Seashore

Click HERE for a map of the location from Google Maps

Time: Doors open at 3:00pm pdt, first transmission 5:01pm pdt (0001gmt 13 July)

Refreshments: Served

Photographs: Encouraged

Tours: Given

None of this would have been possible without the trust and vision of the Point Reyes National Seashore . The only reason these facilities were spared the bulldozer that visited all the others is that they are on park land. And the only reason they have been restored to operation is that the PRNS staff understood their importance and trusted the MRHS to restore them to life.

MRHS Stations

Notice: At press time we have not received authorization to use the KPH and KFS frequencies. A special update will be sent when final information is received.

Sixteen transmitters will be on the air from the MRHS transmitter site in Bolinas. That doesn't include transmitters held in ready reserve in case of failure. Members of the crack MRHS Transmitter Department and the H Set Team will be on hand to assure that all goes well.

> KPH:

Frequency Transmitter Antenna

500/426 Henry MF-5000D Marconi T (Off the air, antenna down)

4247.0 RCA K Set Double Extended Zepp
6477.5 RCA K Set Double Extended Zepp
8642.0 RCA L Set Double Extended Zepp
12808.5 RCA L Set H over 2
17016.8 RCA L Set H over 2

22477.5 RCA H Set H over 2

The restoration of the H set has been chronicled in past issues of the Newsletter. It will return to revenue service for the first time in decades for Night of Nights. See Newsletter No. 38 for information about and photos of this magnificent transmitter.

> KFS

We want to offer our sincere thanks to Globe Wireless for the help and support they have provided for our project since the very beginning.

21050.0 Henry HF-5000D H over 2

> Reception Reports

Reception reports and verification requests for the MRHS stations listed above may be sent to:

Maritime Radio Historical Society
PO Box 392
Point Reyes Station, CA 94956
USA

> Station Telephone

The receive site may be contacted by phone on 415-669-9646

> Hear about Night of Nights on KWMR

Community radio station in Point Reyes Station will broadcast a special presentation about Night of Nights on the Epicenter program at 5:00pm Pacific time 8 July. Listen directly to KWMR on 90.5 Point Reyes, 89.9 Bolinas or 92.3 in the San Geronimo Valley. Not in the listening area? No problem. Listen on line via the KWMR Website . Just click on Click to Play. Can't listen at that time? Again, no problem. Listen to the KWMR archive of the program. Click on the date, 8 July, and the program name, Epicenter.

USCG Stations

NOTICE!

This may very well be the last time ever that USCG stations can be heard on the air using A1A (Morse) emission. As new equipment is installed the hardware and wiring for Morse has been progressively removed. And the personnel who knowledgeable in the art retire or are reassigned. So be sure to listen for these stations.

Many USCG personnel at all levels are responsible for bringing these stations back on the air for Night of Nights 2104. We want to particularly thank ET1 Mike Leska and Chief Eric Simmons (Ret.) for taking the lead for this year's project.

NMC/NMQ verification card from Night of Nights 2014

> NMC (Transmit Bolinas, Receive Pt. Reyes)

Frequency Transmitter Antenna

472.0 Nautel ND2500TT/6 173' monopole tower
500.0 Nautel ND2500TT/6 173' monopole tower
6383.0 Rockwell-Collins RT-2200 Omni-directional
8574.0 Rockwell-Collins RT-2200 Omni-directional
17220.5 Rockwell-Collins RT-2200 Omni-directional

NOTE regarding NMC/NMQ/NMW MF transmissions. Only one MF transmitter will be in service at each station. Morse transmissions will be made on an as-available basis from each station as USCG operators must also accommodate scheduled NAVTEX transmissions.

> NMQ (Transmit Cambria, CA, Receive and Control Pt. Reyes)

NMQ Transmitters

Frequency Transmitter Antenna

448.0 Nautel ND2500TT/6 Inverted L
500.0 Nautel ND2500TT/6 Inverted L

> NMW (Transmit Astoria, OR, Receive and Control Pt. Reyes)

Frequency Transmitter Antenna

448.0 Nautel ND2500TT/6 Capacitive top hat
500.0 Nautel ND2500TT/6 Capacitive top hat

> Reception Reports

Reception reports and verification requests for the USCG stations listed above may be sent to:

Attn: OSCS Phil Marsh
USCG CAMSPAC Point Reyes
17000 Sir Francis Drake Blvd.
Point Reyes Station, CA 94956
USA

Shipcom LLC Stations

All thanks to Rene at WLO and CJ at KLB for the work they do each year to bring these stations back on the air. They are true radiomen.

> WLO

2055.5
4343.0
8658.0
12992.0
16968.5

> KLB

488.0
500.0
8582.5

> Reception Reports

Via email (for both stations) to: wloradio@...

> W4WLO

Here's great information just received from Rene Steigler of WLO:

We will activate W4WLO ON 40 and 20 meter CW for Night of Nights. We are thinking 7055/14055 so as not to interfere with K6KPH.

Be sure to listen for W4WLO and give them a buzz.

> Calling Channels

All commercial and USCG stations listed above will listen for calls from ships on 500kc and on ITU Channel 3 HF:

4184.0
6276.0
8368.0
12552.0
16736.0
22280.5

Listen on these frequencies if you want to copy both sides of ship to shore contacts.

> Commemorative Messages

Was your father, uncle or grand dad a commercial op or amateur operator? Would you like to send a commemorative message in their honor over KPH, KFS and KSM? We have sent several of these messages in past events and they were all very moving. If you would like us to send such a message this year please send it to us no later than Wednesday 9 July pdt so we can be sure to include it. Sent it to info@...

> Attend a special presentation on the history of KPH

The Novato, CA library has kindly invited Chief Operator Dillman to present his famous lecture and slide show on the history of wireless in West Marin at 6:00pm on 29 July. The presentation will cover in detail the span of this dramatic story from the establishment of the first Marconi stations at Bolinas and Marshall in 1914 including both trans-oceanic operations and the history of KPH.

Many photograph that have never before been seen in public will be shown. If the history of maritime communications is an interest of yours, this presentation is not to be missed. The Novato library can accommodate 60 people. There are still a few good seats left. So mark your calendar and join us at this event.

Date: 29 July 2015
Time: 6:00 pm
Location: Novato library, 1720 Novato Blvd, Novato CA 94947

Phone: +1 415-473-2050
Google Maps: Click HERE

> Project to rebuild a RCA SSB R3 diversity receiver!

This should probably be the headline story for this issue of the Newsletter. In fact if this wasn't the Night of Nights special issue, it would have been. Hold on to your earphones: the MRHS has plans to rebuild a RCA SSB R3 diversity receiver! This is real Jurassic Park stuff.

If that statement doesn't quite cause you to gasp in amazement then we refer you to information about the magnificent R3 in Newsletter No. 16 and Newsletter No. 19 . At the time this information was written the crack H Set Crew had completed three years of work to bring T3 transmitter 298 on line at Bolinas. The T3 is a four channel independent sideband transmitter used in trans-oceanic point to point service. But we never expected to have the companion R3 diversity receiver to show visitors. There once were dozens of these receivers in the receiving room upstairs at Point Reyes. But they had all gone to the dump, leaving us with just a few fragments.

Now comes a overseas seller with just about all the components needed to rebuild a R3! Needless to say we struck a deal for everything he had, figuring that True Believers would approve of this expenditure of the funds they had donated to the MRHS.

At press time the status is that everything is in a wooden crate undergoing customs inspection in New York. We have to wonder what they will make of this stuff! Once the crate is released by customs we assume it will be loaded on a truck for shipment to San Francisco.

We have to say that the business of international shipping is complex, with endless forms and the need for brokers and agents. Nevertheless, if this effort produces a complete and working R3 receiver that we can show folks when they visit, we think it will be worth it.

Where to put the receiver? Sadly, it can't go back into the receiving room at Point Reyes. That room is now Park Service offices. But! The receivers for the last point to point link were actually installed just outside the CW operations room while the receiving room was being torn apart of a satellite Earth station. So our plan is to install the completed receiver in that same space, completing the circle and returning a functioning R3 to the very spot where one of its magnificent brothers once stood.

Of course we will keep you posted on our progress.

> 1925 Radiomarine IP-501-A Receiver Obtained by MRHS

When we started the KPH restoration project back in 1999 one of the first things we did was to gather up all the historic photographs of the station and go over them carefully and repeatedly to extract and absorb all the important details they contained. One of our favorite photos is of the KPH receive position taken in 1920. The station had just moved to the original Marconi trans-oceanic receive site at Marshall. As always, the KPH operation had secondary status and the ops were relegated to a corner of the building, huddled over their receivers, their Western Electric 509 headphones clamped to their heads, their Underwood mills at the ready.

KPH ops on duty at Marshall

There are lots of details in the photo including the land line telegraph sounder to the left, chattering out messages from Bolinas and San Francisco in American Morse. Yep, the operators had to be bilingual in Morse. But if course it's the IP-501 receivers that draw the eye of the True Believer .

The IP-501, made primarily by Wireless Specialty Apparatus Co., was the standard commercial receiver of the day, used aboard ship and at coast stations like KPH and WUP of the US Army at Ft. Mills in the Philippine Islands (below) .

It used a single tube as the detector although provision was made for the use of an external crystal detector. Note the external two step audio amplifier connected to the right of each receiver in the KPH photo. This allowed excellent headphone volume as well as the ability to use a horn speaker.

For years we mooned over these receivers, hoping to add one to our collection. We wanted one for two reasons: for display to visitors and so we could experience what it was like to operate one of these receivers, so different from a modern receiver or even a 70 year old receiver from WWII.

We suppose there's something to the saying that all things come to those who wait because an IP-501-A receiver recently became available. The A model incorporates the two step audio amplifier in the receiver cabinet. The receiver on offer was expensive but in superb condition. Plus it was made by Radiomarine, thus providing direct lineage to RCA and KPH. So, after much discussion, we decided to make the purchase.

When the receiver arrived, MRHS members gathered with great reverence to observe its careful unpacking. It was everything we hoped it would be. Luckily, one of our number, Steve Sparks, has an IP-501. He is also a radio historian and a gifted radio diagnostician. He took charge of the slow and careful process of bringing the receiver to operational status.

One of the first orders of business, after checking the tubes (all RCA, by the way), was to select the correct grid leak resistor for stable operation.

That's when we discovered that, yes Virginia, there really *is* such a thing as a grid leak drip pan!

We don't know why but for some reason we found it astounding to see that a resistor manufacturer of the 1920s had enough of a sense of humor to produce these as promotional items. They must be rare as chicken lips. Anyway, we had never seen any before.

After the hilarity died down we returned to work. Life giving voltages were applied to the proper terminals. The tubes grew warm. The earphones came alive. The receiver was in great shape, requiring only a little tweaking (and a bit of a steep learning curve on our part). Then it came time to attach an antenna to see what we could hear. The tuning range of the receiver is 300 to 8000 meters (38kc to 1Mc). Our targets were the non-directional beacons at the local airports. We used a selective voltmeter to assure that signals could be heard on the hastily strung up wire antenna (the Marconi T antenna overloaded the receiver). Then we tuned for those signals on the IP-501-A.

Bob Dildine tunes the selective voltmeter while Steve Sparks manipulates the controls of the
IP-501-A.

It was old guys working with old radio gear at an old receive site on a foggy day at Point Reyes. How much better can it get? Well, we guess it got maybe even a little better when we placed the IP-501-A on a special table to had made just for it and placed the horn speaker on top. Not just any horn speaker, mind, but the exact same make and model horn speaker we see in photos of KPH at Marshall.

The IP-501-A on its custom made table, with horn speaker, in the main hall of the receive site at Point Reyes

Now, how about the reception of some signals in the MF marine band? Our plan is to tune the receiver to the KSM 426kc signal to demonstrate it to visitors. But alas, as noted above, our MF transmit antenna is on the ground. But! MRHS Transmitter Supervisor Steve Hawes is also a member of the radio department (in fact, he *is* the radio department) aboard SS RED OAK VICTORY/KYVM . The ship, with Steve at the key, was on the air on 6 June (D-Day) on MF and we copied his 500kc signals on the IP-501-A!

Here are some notes from Steve Sparks on the work we did on the receiver:

Before applying power to the receiver, we first checked audio transformers, fixed and variable condensers, and the grid leak. Everything was good except for one open solder joint. We installed tested tubes and were able to hear things. Operation of the controls was puzzling until we discovered that two knobs were installed 180 degrees out of correct alignment, making the primary circuit tuning knob tune backwards and reversing the sense of the coupling control. Excessive howling was greatly improved with the installation of a slightly lower value grid-leak resistor. Using a long feed line as an antenna seemed to be causing overload, so we put up a 100 foot wire and that worked better. Impulse noise was reduced with a common-mode power line filter on the power supply. With that final improvement, we were able to log four NDBs at mid-day, the farthest being FCH Fresno 344 kc, about two hundred miles away.
Steve

Partial view of the Treasure Room. Strict rule: no drooling.

The next step is for you to join us at the receive site some Saturday. Identify yourself as a True Believer for admission to our Treasure Room where the IP-501-A and many other items of interest reside.

> Another Receiver!

Another historic Radiomarine receiver has recently arrived. Actually there are three components involved: receiver CRM-46092, preselector AR-8503-P and power supply CRM-20096, known collectively by the military as RAZ-1.

This receiver is the direct descendant of the IP-501-A, replacing it in most shipboard installations. It covers 15kc to 600kc in four ranges. While it is clearly a more modern and easier to use receiver, it's amazing how many features and similarities it has with the IP-501-A. At this writing the components have been cleaned and inspected. Much to our relief all three units appear unmodified and in excellent condition. Like its IP-501-A older brother, The CRM-46092 will be brought to life for display and use at the MRHS.

Flash!

Just before press time life giving voltages were applied to the RAZ-1. All components came up and functioned as they should! It just shows the result careful engineering and quality

construction. Non directional beacons and WWVB at 60kc were received without difficulty in daylight.

The receiver, preselector and power supply will be properly mounted and prepared for display to visitors. Plus we plan to use it to monitor 500kc and the KSM transmissions on 426kc.

> And Yet ANOTHER Receiver!

We are very fortunate to have in our collection the descendant of the CRM-46092, the Radiomarine AR-8510. This is the main ship receiver that was supplied with the Radiomarine 3U and 4U radio consoles. It was also used at some coast stations, including post war KPH.

This receiver too will be restored to operational status.

In combination, these three receivers will permit us to show the history and development of marine receivers from the 1920s through WWII and beyond, since many of the Victory and Liberty ships that were activated for the war in Viet Nam were equipped with 3U and 4U consoles.

Once restored, all three receivers will be placed in the Treasure Room at the receive site. When you come to visit, be sure to whisper the words "True Believer" to a MRHS member for a Treasure Room viewing opportunity.

> Frank Geisel's Report No. 3 June/July 1946

Beginning in Newsletter No 49 we began presenting FG's KPH reports from the years immediately following WWII after the station was re-opened for commercial service. Let's look in at his reports for

June and July 1946 as Frank continues to battle interference, ships that won't call KPH to clear traffic and operators who find life in West Marin too rugged and expensive.

In June the good news was that the installation of a crystal oscillator in BL2 was completed. However the key clicks from VFN were so broad they were interfering with KPH on 8420kc. Message levels were fairly good. A new man hired last month, N.C. Kumler, decided West Marin wasn't for him and departed..

In July

> MRHS Merchandise

Support the MRHS and look cool at the same time. Such a deal! We've got hats, mugs, T shirts, belt buckles and bumper stickers, all with variations of the MRHS logo. Get a hat and mug for yourself and a put yourself in solid with the XYL by getting her a MRHS hoodie.

Click on the images to go to the True Believers Store

Just click on the images above to go to the MRHS True Believers store and browse our offerings. Thanks!

Whew! Okay, that's it for this issue. Thanks for reading. We very much look forward to hearing you on the air or seeing you in person on Night of Nights. Until then we wish you the best of luck and fair winds & following seas.

73,

MRHS

Don, LOTW is the Logbook of the World. Its run by the ARRL and is used
for QSLing, electronic style, and keeping up with various ARRL awards, like
DXCC, etc. I think you have to have a compatible logging program to upload
your log extracts and the other guy the same. Then the LOTW will match up
QSOs, etc. Takes place of paper cards. I don't use it and don't know much
abt it, but that's the gen. jist. Any one using it and can explain better?
73 de Bill K4JYS

The RBN is pretty neat...eh. I use it quite a lot to see if I'm getting out. I get
a few surprises sometimes too.

Hello Bob W2AMI,
Good to hear from you OM! If you have a bad HK24 triode in yoiur Stancor 60P look no further. I have a 60P and a NIB HK24 spare I can give you, just send me something to my email address to let me know for sure (n3ibx@...).

Perhaps we can have a 60P to 60P QSO someday. Mine will do 30W out on 'Fone modulated by 6L6G's, and about 40 plus on CW. The plate current is just over 100 ma when properly loaded.
You tune your oscillator for maximum smoke,(switch position #1) then (position #3 for plate current) dip to about 110ma. and you'll be good to go.Switch position number 2 reads modulator current.

At resonance the diminuitive HK24 tantalum plate will glow a bright cherry orange just like it's big brother be-tantalumed triodes. The spare and tube I have in my transmitter isn't a Eimac but something else I think. It'll still work FBOM for you.

Hope to hear from you soon and very best regards. Hello to the XYL from me.

Joe Cro N3IBX

I was down in the vintage shack just now looking for something and decided to fire up the 1920s style AM rig I built early this year. It is a 171A Hartley modulated bya 01A which is in series with the B- for the 171A and controlled by a carbon mic circuit. Mic bias is stolen from the 01As battery heater supply. It is amazing to me how this old stuff works and it is hard not to grin a bit when playing with it. If one had this stuff back then you would have thought you were king!

I use LoTW and your description is about right. As a DXer LoTW has been a godsend for me. I only wish more people would use it. Many logging programs automate the process, as does the one I use. However just about all logging programs probably have the ability to export the log as an ADIF format file, which with a bit more effort can be uploaded to LoTW.

Hi Joe aka n3ibx
Nice hear from you.
I had other group replies with HK info - tnx to all.
Joe, we might be the only two Stancor 60-P xmtr owners in the world :-)
I also have the ST-202-A, S-282 and 440M.
Tnx for the HK-24 offer.
Talk to u off group.

It turns out this is a Ross Hull design. His article describing it is in
the June '30 issue of QST. The main point of the article is the gain of
the '33 used as the AF stage but the radio is less than half the size of
the SW3.

The 33 is missing from mine. Does anyone have one to spare?

Don,

Glad you enjoyed the blog and website.

Most of my summer operating is in the park. I like to get out when I can here in MN. This coming Saturday mid day I'll be portable using my KX3 on 20 CW (around 14060) at Frontenac State Park, about an hour from here. The picnic area at Frontenac is on a 300' bluff overlooking the Mississippi. Great propagation to the east.

During the winter is when I get the most use out of my boat anchors in the basement, mostly during the AWA BK and LC CW Parties. But I do have my Utah Jr and HRO Sr set up right now. We might be able to QSO on 40...say around 7035 or 7110. Shall we try an evening sched?

I have a internal repair to perform on my 40M boat anchor (WS No 19) Something in the PA smelt funny but no real smoke and output dropped. Probably the cap to ground is going bad after 72 years. It was the piont of trouble with all my ARC5s so I am used to the signs. But I will listen around on 20 with my modern rig on saturday just in case. I have two rigs on 80M but this time of year 80M can be a bit iffy although Lou and I pulled it off a couple of weeks back with my breadboard station. You are probably about 500 to 600 miles ATCF from me but I will check.
Hope you find a 33 for your regen. Love the thru the hole tube.

Good News To Report!

> MF Antenna Restored

> KPH and KFS Frequencies Confirmed

> Clarification: Sunday is the Day

> MF Antenna Restored - Your Donation Dollars at Work!

Readers of these pages will doubtless recall that for some time now we have been sharing tales of woe about winter storms, antennas down and how much it will all cost to make things right. Many True Believers stepped up to make contributions, which we have carefully set aside in our bank account.

As we have reported, a December storm took down one of the three poles supporting the Marconi T MF antenna at Bolinas. As Night of Night approached we realized it was impossible to think about the event with no signals on 500kc and 426kc.

A crack restoration team was assembled. We dipped into the funds supplied by our generous donors to buy materials and hire expert climbers. Today we headed out to the Bolinas antenna field with the steadfast objective of restoring the Marconi T. This evening we are tired, sun burned and worried about any poison oak we may have picked up. But! We hare exceedingly happy to report that... The Marconi T has been restored!

Climber ascends the 100ft center support pole for the Marconi T antenna next to the tuning house, Building 42

The Marconi T is the largest antenna at the site. The center vertical radiator is 95ft tall. The top capacity hat consists of two wires with an total span of 736ft.

Our objective was to restore the vertical radiator, restore one span of the top hat to the still standing pole, then restore the second half to a pole as close as possible to the location of the downed pole.

Climber on the center pole watches as the center radiator is pulled up toward him by the ground crew

Step by step the work progressed. The first two goals were met with relative ease but the third was a challenge. We had to support the other leg of the capacity hat in the middle of its span with an insulator mounted on an intermediate pole. A pulley was installed and the support successfully hoisted up.

One of the pulleys used for the Marconi T restoration, retrieved from KPH stock

Then we had to pick a pole at the right distance and direction to stand in for the one that's down. Luckily one of the poles for one of the H over 2 antennas fit the bill. After much bushwhacking we were able to install a pulley on that pole as well and hoist up the the final span of the capacity hat.

Climber installs a pulley atop one of the Marconi T end poles

There is still one major task ahead of us: re-tuning the antenna tuning unit to match the new antenna which will almost certainly have slightly different characteristics compared to the original antenna. But we have a special crew ligned up to do this on Saturday, just in time for Night of Nights. So, if all goes well, we will be back on MF in time for the event.

> KPH and KFS Frequencies Confirmed

In Newsletter No. 51 we mentioned that at press time our use of frequencies for KPH had not been confirmed. We are very pleased to report that confirmation has now been received so stations KPH, KFS and KSM will be on the air from our Bolinas site.

Happy listening!

Check Newsletter No. 51 for a complete listing of frequencies for all Night of Nights stations.

> Clarification: Sunday is the Day

There's no such thing as a shortcut. This was brought home to us when we used last year's Night of Nights announcement as a template for the 2015 announcement.

As many readers were kind enough to report, the wrong day for Night of Nights 2015 was mentioned. We apologize for the confusion. Here below is the correct information for the event:

Date: Sunday 12 July 2015 Pacific Daylight Time

Location: RCA receiving station, 17400 Sir Francis Drake Blvd., Point Reyes National Seashore

Click HERE for a map of the location from Google Maps

Time: Doors open at 3:00pm pdt, first transmission 5:01pm pdt (0001gmt 13 July)

Refreshments: Served

Photographs: Encouraged

Tours: Given

None of this would have been possible without the trust and vision of the Point Reyes National Seashore . The only reason these facilities were spared the bulldozer that visited all the others is that they are on park land. And the only reason they have been restored to operation is that the PRNS staff understood their importance and trusted the MRHS to restore them to life.

> MRHS Merchandise

Support the MRHS and look cool at the same time. Such a deal! We've got hats, mugs, T shirts, belt buckles and bumper stickers, all with variations of the MRHS logo. Get a hat and mug for yourself and a put yourself in solid with the XYL by getting her a MRHS hoodie.

Click on the images to go to the True Believers Store

Just click on the images above to go to the MRHS True Believers store and browse our offerings. Thanks!

Thanks for reading this Night of Nights update. We very much look forward to hearing you on the air or seeing you in person on Night of Nights. Until then we wish you the best of luck and fair winds & following seas.

From: JAMES HANLON
Topic: 11561 Message: 11561

Neil,

Per your AWA post about the Unusual Regenerative Receiver, I went looking in my stash and I found a 33 you might want. It's a Cunningham C333 with a sort of tear-drop shaped bulb. There's a label on it that says "OK May 40." I just tested it on my trusty old Hickok 533 and it came up way into the green zone, above the nominal transconductance.

It's yours for the shipping cost. Interested?

Jim Hanlon, W8KGI

11565. Breadboard on new PSU

Yahoo group: AWAGroup (2014 — 2016)
Date: 2015-07-11 06:05:50 UTC
From: dulmagedon@...
Topic: 11565 Message: 11565

I had my breadboard rig on an old PSU I made some years ago. I use it on my 29 radios as it has variable DC voltage for the heaters .It worked ok. Always had a bit if a hum despite my efforts to get rid if it but a handy piece none the less. I was in the shack playing today as it was for a bit too hot outside and realized the lower high voltage for the new PSU I built for my no19 will run it (the 6l6 breadboard rig) as well. Designed to supply approx 275 volts under load. it came in pretty close with loaded voltage of 282v. T(he PSU supplies 12vs DC for the military sets on pins 7 and 6 but also supplies 6.3 AC on pins 7 and 2 (pin seven being also ground) I use 7AC socket pinout for all PSUs and all radios in the shack. It eliminate mistakes. Pin 3 (plate) always has the moderate hi voltage Cathode comes out 8 and is also ground. Unusual hi voltages always come out the screen pin so any radio can be plugged into any PSU and only the proper voltages are delivered. So I plugged the breadboard rig into the new PSU. Everything looked good.
I hit the key after a few minutes warm up Nice. Without the voltage sag of the old light duty PSU the note was noticeably different. I spent the afternoon playing with several tubes , both 6v6 and 6l6 varieties. The 6L6G proved the best output even though it could have had probably almost double that for voltage and survive on CW. When adjusted up so everything was happy input power was 11.5 watts. Signal sounded clean on the monitor. Noticeably cleaner then the other PSU and the big transformer wasn't even breaking sweat. The Regen Rx works as well although not as clean as on batteries. Still even though at the time of day CHU could not be heard here on any rxs and antennas I was able to copy w1aw with ease so perhaps all will be well. I will try it again when east west propagation is good. So far I am thinking it is going to work out well.

Don,
I believe that's abt the same TX as in the Dec '29 QST. It is a TNT using a 210.
I see it in my 1933 ARRL handbook as well. I built one using a '01A which
worked pretty good. It was my first '20s rig and used it for several years in
the BK until I built a Hartley. You might be able to find info using TNT or Tuned-
Not-Tuned in your search...and also Dec 1929 QST. Sorry I don't have a
scanner, but I expect some-one on the list can furnish you with the info.

It can't be a 6L6 design in 1932. Octal tubes didn't arrive on the scene
until 1935, and the 6L6 was born in 1936.

I want to explore some 30s circuits. But no more rock control. Based what is found in QST and Handbooks from that period, this might be a problem, Don.

The TNT was still being featured in the '34 hdbuk, but all other oscillator rig circuits found in that edition were C.C.

Have never looked thru a '35 handbook. What type of "beginners rig" circuit was featured there anyone?

73, Lou

How about the ECO and Tri-Tet of the 30's?

You might check out the 6L6 ECO - 809 or 807 PA rig that popped up in the handbooks and HamTips of the 30's.

I've got an 802 ECO - 809 PA rig that I started on several years ago but has fallen low in the build list.

Best I remember, Don, the TNT worked fine. I had to do some tweaking on the grid coil, but other than that worked pretty well from the start. A little chirpy and drifty but thats normal. With a some extra solid construction practice, you might make a pretty stable rig. At first I ran about 150-175vdc on the '01A, so output was very low, probably less than a watt, but made BK QSOs. Later went up a bit higher on B+ (I run 300vdc on a 1924 version of the '01A on the 1924 Meissner...so they can take it). If you don't get the info, I can try to get a copy of the 1929 version off my CD and email to you.

DIrectly heated tubes are complicate things sometimes and I have many of the 29 rigs (Thanks Lou! Its all your fault ;>) I want to explore some 30s circuits. But no more rock control.I have had enough of that. Don't fence me in is my theme song!
So what do you think of the design Bill since you have a real live one. (As you know I am a big fan of the 01a as well. "The little tube that could" and no one realizes it.

I added another rock to my collection to day. I now have 3736, 3561 and 3543 rocks for the breadboard. I think I can find two more at least. I think I have a bit of plan now. However I also have an 10 watt VFO run exciter from the OTHER handbook that is very buildable. I am thinking. OK Bill. Since I want to build it with a indirect heater tube I will just free build it from memory of my TNT with appropriate mods so i can use a indirect heart tube.

Yes that is a problem. This was the era I see as the dark ages. Probably not the wisest decision ever made. I do have a circuit called a 10 watt VFO /exciter in the 1940s OTHER handbook that I have been wanting to build. If it is in the 1940 book then it must have been around before that as Handbooks tend to be a summary of the best designs. It is a 3 tube circuit using a have most of the parts other then two variable caps which I can get with out too much trouble. However I would still , truth be known like to try a slightly modernized version of the TNT with octal tubes or at least not directly heated filament tubes. When modulating from the bottom which I like doing directly heated tubes present some problems which while not insurmountable are inconvenient at the least. I like 6l6s in all flavours and would like to use one in a TNT style circuit so I may just build one free style and see what it is like. And may just leave it on CW too. Other then my 1939 Hammarlund Shortwave manual I have no 1930s books. Only 1920s or 1940s and 1950s. The Hammarlund book has a VFO based 5 meter rig that would lend its self I think to a 40 meter design as well with a bit of minor work. I have just had enough of Crystal controlled HF rigs. A belly full if you will. Even my Dx60B in on the rocks although I did build it a VFO. I watch my early rigs on my digital rx as I monitor my signal with RF gain choked a bit.and no extended antenna. Any change in freq greater then the step will produce a note change in tone and once tuned up and running other then hand effect I find then sitting proper and not wandering around. One in particular I built doesnt even have hand effect. It is an AM two tube circuit using a 6sl7 osc modulator driving a 6v6 or 6l6 depending on power supply used. It is screen modulated and has a carbon mic battery biased circuit up front. It was kinda a free build and I have had it now a few years and have constantly rubbed on it till i have it working as I wished. Like all well rubbed on radios it shows its rubbing.

I have ARRL Handbooks from 1931 and 1935. In the 1931 Handbook, the "Single Control Transmitter" is a UX-210 in a TNT circuit with the antenna tapped onto the plate coil through a .002 mfd condenser. A 500 volt power supply is specified. Coils are described for 160, 80, 40 and 20. By 1935 it had evolved slightly, using a 10 and link coupling to the plate coil. In the 1931 version the unturned grid coil was at the right-front of the breadboard, axis perpendicular to the plate coil axis. In the 1935 version it is on the right edge of the breadboard, axis parallel to the plate coil axis. It still uses the same power supply, and the coils are exactly the same.

I checked with QST, and the 1931 Handbook transmitter is the same one described by George Grammer in December, 1929 starting on page 25, "The Single Control Transmitter." There's one difference, Grammer did not include coils for 160, just for 80, 40, and 20.

Hi Jim and tks...

So, this is what you are seeing below in the '35 edition?

Anyone... Were self-excited oscillator transmitters outlawed or just discouraged in the US?

From '34 handbook.

11583. Self-Excited Rigs Not Outlawed

Yahoo group: AWAGroup (2014 — 2016)
Date: 2015-07-14 18:15:36 UTC
From: JAMES HANLON
Topic: 11583 Message: 11583

Self-Excited rigs were never outlawed in the US, but by 1934 it was becoming obvious that one could build a one-tube crystal controlled rig that would be a lot easier to adjust and that would out perform the typical self-excited TNT or Hartley for not much more than the cost of the Self-Excited rig. Certainly one QST article that helped this transition along is "A One-Tube Crystal-Controlled Transmitter, Practical Two-Band Operation With One Crystal," by George Grammar, QST, March 1934, page 8 and following. It describes a 59 pentode used in a Tri-Tet circuit for either 160 and 80 meters, 80 and 40 meters, or 40 and 20 meters. Output on the crystal fundamental frequency was about 7 watts with about 5 watts out on the second harmonic. You could even get a watt or so out on the fourth harmonic, and on 20 meters it can be quite surprising how far you can go on even that power level at the right time.

The QST Editor, K. B. Warner, put the following note at the head of the article. "QST's most recent development - the Tri-tet oscillator - has made the single-tube crystal transmitter a really practical affair at last. Practical because it is now possible to work equally well in two - and, in a pinch, in three amateur bands with a single crystal. Unless we miss our bet, this particular set marks the beginning of the era in which the new amateur's first transmitter will be crystal controlled. The design of the set is such that other higher power units of similar type can be added at will."

This transmitter, along with the type 10 TNT, was featured as a beginner's transmitter in the 1935 ARRL Handbook.

Just a side note, the 1931 Handbook shows a 150 watt, self-excited oscillator transmitter for 20 and 10 meters using push-pull 852s. That must have put out an interesting signal!

In the later 30s, crystal-controlled transmitters became pretty much the rule. By 1938 some folks were building "ECOs," low-powered Electron Coupled (variable frequency, self-excited) Oscillators (using tetrodes or pentodes with oscillation accomplished between the control and screen grids and coupled via the electron stream to the plate circuit for output), to drive the crystal oscillator stages in their rigs. See for example, "A Two-Tube E.C.O., "Beveridge, QST, August 1938, page 28; "Switched 6L6G Oscillator for Grid-Plate Crystal and ECO Operation," QST, May 1938, page 55; "An ECO of High Stability and Output," Guimont, QST August 1938, p 29 and October, page 109; "A Stabilized EC Oscillator," Scoville, QST August 1938, page 29; " A High-Frequency Exciter of Variable Frequency and High Stability," QST, July 1938, page 52; "Variable Frequency Control for Transmitters," Griffin, QST November 1938, page 28. Meissner introduced their "Signal Shifter," a self-contained 6F6/6L6 ECO Exciter with a built-in power supply and plug-in coils covering 160 through 10 meters in February 1938.

So from the early 30s to the later 30s, self-excited oscillators evolved from single-tube or two-tube push-pull triode jobs intended to deliver quite a few watts to the antenna by themselves to more sophisticated, Electron-Coupled tetrode or pentode, low power circuits, most often with one or more buffer stages following the oscillator, designed for stability and intended to drive the higher power stages of a multi-stage transmitter.

11584. Setting up the vintage station

Yahoo group: AWAGroup (2014 — 2016)
Date: 2015-07-14 22:59:30 UTC
From: dulmagedon@...
Topic: 11584 Message: 11584

With the breadboard rig running nicely I needed to move it to a more period correct spot in my vintage shack. Years ago we bought an old house and flipped it. 120 years old then and it had a handmade small table painted a generous coat of green paint. It had had a rough life but we still have it so It is now the table for my vintage station. Over the table I installed a porcelain light socket and installed a Nostalgia bulb (Lowes) which is said to look like Thomas Es original. A small power supply easily hidden that I had built for the BK now powers the sets. Had to rework my feedline so it would come into the shack more but just now fired it up, waited for warm up and sent CQ. Much to my surprise I got an answer from about 70Miles north of here. The band went to pot quickly but I was able to get in most of one exchange. Was using my new rock I found in my old stash. 3541kcs. Normally 70miles would be a bit close but for a few moments he was clear as a bell. May play later this evening after 9 if I am not too tired.
Jim, thanks for the history. Was poking away at the 6l6 tnt project today. No rush but it is on the bench. Meanwhile I may be having too much fun.

From: dulmagedon@...
Topic: 11584 Message: 11589

Went on tonight just now the same fellow was waiting for me VE3DCX and came back immediately. Fading was bad and noise level very high but when it was good it was pretty good.Eventually after a few handovers it got too bad to continue. Still is a ball running the old style station.
Also this morning I dragged by bad No 19 set out. It is pretty rough and looks like it was sunk in water or something as the chassis an even the right handle is rusted. It was missing two tubes but I had them so popped them in. Sprayed contact cleaner on all the switches and cycled them till they felt free. I then hooked up my vibrator power supply with clip leads and lit it up. Darn thing works! Not perfectly but audio output, volume works BFo works , Spotting works and AVC works. Rf gain which is this sets claim to fame (this is a Mk 111) works and even though there were no stations on air at that time I can hear the antenna make its connection which is a good place to start. It had an intermittent and I traced i tto the 6k7 on the right hand middle side. When I tried to remove the shield it would not budge . Eventually I got it loose but the tube did not survive. There is one in the intercom that I don,t use or run so for now I can steal it.
I am amazed that a radio in this condition still functions. Now What?

I have been pursuing this project on the side since we talked about it. The tube is installed and wired along with shunt feed. I wont need as many parts because of the indirect heating of the filament no heater/kathode splitter network will be needed. I have the variable cap yet to mount and large tank coil to wind. I am building from memory and was ding well till I started making the grid coil. I made one but it is too low when installed so off with some windings. This will not be a pretty build as this chassis is my 6l6 experimental work piece and has more holes then an unused mailbox. I am having evil thoughts as I build. Why don't I do an 811A TNT? I already have a 211 but wasn't happy with it (although I still have it more or less all there.) Anyway it is happening. I ran into VE3DCX while operating my breadboard station . Turns out he is building a 1929 BK style rig. He is a pretty good operator. Is able to find you very quickly so he must constantly be checking. His CW is easy copy. He asked if 2a3 are legit for Bk. I believe they are . My search showed 1924. Any comment? He asked what I use. I was honest and said I have used 45s but prefer those little ruf and ready 01As. He has a bunch of all three tubes. Oh yeah. I had the 40m hartley AM rig on the bigger PSU the other night. Sounded great. But I discovered why power is sometimes reduced in AM mode. I was halfway into my second Cq call and the 171A started to turn orange. I shut of the modulator but it was too late as it went bright white before I could shut off all power. I felt like the guy who pulled out his tie and wet his pants. I haven't had the nerve to fire it back up on its old supply and see but I suspect it has passed on. However I do have Lou's old 45 . I better treat it with respect.

Hi Don,

I'm not sure of the exact year, but the 2A3 came out in the early-mid
1930s. Definitely not "legit" for the BK.

Ok Larry I will tell him. The RM site said 1924 so that is why I said that. Wouldn't be the first time they were incorrect. BTW I see your name as king of the AM contest. Let me take a moment to congratulate you. Nice job!
All this talk of the old rigs had me firing up my BK Hartley this afternoon. Once I got it lit I took the 171A I made glow in the dark and tried it. Works good. How it survived that I don't know but I am glad it did. I guess it is heat treated now.
Ah the shield connection. Good reminder. However I have to date never had a steel 6l6 in these mittens. Sometimes I wish I had a couple but so far no luck. I did a lot more on the 6l6 TNT this afternoon. Using already built stuff for most . coils, chokes etc etc so it is more assembly then anything. I am curious to see how it works.

Subject: [AWA Group] 6L6 TNT

I have been pursuing this project on the side since we talked about it. The tube is installed and wired along with shunt feed. I wont need as many parts because of the indirect heating of the filament no heater/kathode splitter network will be needed. I have the variable cap yet to mount and large tank coil to wind. I am building from memory and was ding well till I started making the grid coil. I made one but it is too low when installed so off with some windings. This will not be a pretty build as this chassis is my 6l6 experimental work piece and has more holes then an unused mailbox. I am having evil thoughts as I build. Why don't I do an 811A TNT? I already have a 211 but wasn't happy with it (although I still have it more or less all there.) Anyway it is happening. I ran into VE3DCX while operating my breadboard station . Turns out he is building a 1929 BK style rig. He is a pretty good operator. Is able to find you very quickly so he must constantly be checking. His CW is easy copy. He asked if 2a3 are legit for Bk. I believe they are . My search showed 1924. Any comment? He asked what I use. I was honest and said I have used 45s but prefer those little ruf and ready 01As. He has a bunch of all three tubes. Oh yeah. I had the 40m hartley AM rig on the bigger PSU the other night. Sounded great. But I discovered why power is sometimes reduced in AM mode. I was halfway into my second Cq call and the 171A started to turn orange. I shut of the modulator but it was too late as it went bright white before I could shut off all power. I felt like the guy who pulled out his tie and wet his pants. I haven't had the nerve to fire it back up on its old supply and see but I suspect it has passed on. However I do have Lou's old 45 . I better treat it with respect.

Thanks, Don. I'm not familiar with the "RM site." Do you have a link?

As far as the AM contest goes, I was really surprised, because I spent a lot of the time as W2AN, which took away from operating as NE1S. I was one of very few people who bothered to send in a log, as I understand it. AMers are notorious for disliking paperwork! I've won it (more legitimately) twice before.

The screen grid may (or may not) interfere with proper oscillation as a TNT, if you connect the tube as a tetrode. The reason is the Cgp, which is part of the feedback loop, may be too small to sustain oscillation. Let us know how you make out. If you do have problems, you could try connecting the screen grid to the control grid and operate it as a triode. You could also try connecting the screen grid to the plate in a low-mu triode connection, but in this hookup you shouldn't exceed 300V on the plate/screen.

If not, add external capacity?

Ok, I'll watch for that. I did build a Hartley 6l6 last fall and ran it for awhile. I am really curious to see if/how it works. I just poke away at it when I am in the shack "reading the mail" but it is coming along well. It aint pretty though. I really hope I don't have to triode connect it but we shall see.

2a3, I searched an English site. Other was in German. Date of first production as you said Larry 1936. Other site was apparently referring to the date of the 4 pin socket introduction (UX I think it is called) I saw the 1924 date and jumped to conclusions. Why that would be on the tube info is anyones guess. I went back and read it carefully then looked for another site. RM is Radio Museum. Often has info but always they want money and often it is in only the language of the submitter unless you join or pay. One can only pay for so much. I have my limits. RM is a Swiss entity so info is often in German, French, Italian or English

Yes, that would work too. But it involves adding a component, while connecting the 6L6 as a triode would eliminate at least one component. Another thing to try might be to just eliminate the screen grid bypass capacitor, and let the screen float at RF, effectively increasing Cgp. This, as well as the triode connections, would reduce the gain (vs. the tetrode connection), which is probably desirable for a TNT (high gain tube -> less stability and more squirrelyness).

Whatever. Wish these tube history websites would all get together. Anyway I have informed the fellow not legal for BK so I did my part.
Meanwhile , back at the ranch I finished the project. The answer is a no. Neither normal connected, bypassed or not. triode connected or screen floated. Voltage checks looked good for all elements and I tried a 6v6 too just to see. My grid coil and tank are on the same frequency so my question has been answered. Now I could find an indirectly heated triode tube and pop it in that would work with a socket rewire but I don't need another rig. I just wanted to know if a single 6l6 could be easily built TNT.and now I do. Curious I guess.

Hi Don,
I am not certain that I understand correctly, but I believe that you are stating that your tnt will not oscillate????
The plate tank circuit of a tptg/tnt oscillator must be tuned to a somewhat higher freq than the grid circuit, in order to provide feedback in the proper phase to induce oscillation. If detuning the plate tank circuit toward the high freq side of the grid tank resonant freq does not induce oscillation, you might try adding a "gimmick" cap between the plate and grid, to increase the feedback.
I can't imagine this being necessary, at HF, with a 6L6, however. Perhaps the grid tank circuit is very lossy, or not tuned to the freq that you believe it is?? If you are determining the grid tank resonant freq with a GDO, etc., make certain that this test is performed with the 6L6 in the circuit. The resonant freq of such a low "C" tank circuit will be lowered substantially by the sddition of the input (Grid #1/cathode) capacitance of the 6L6 oscillator tube, and it may be too far removed in freq, from the plate tank circuit resonant freq, to permit oscillation.

Good thoughts, Ron.

I think if it were me, and my first effort was unsuccessful after trying a few obvious things, I'd fashion a makeshift adaptor to use his 6L6 in a known-good TNT (or whatever). It would take the coils, etc. out of the equation and prove (or not) the concept of the 6L6 TNT. Also, Don could try the tube from his working TNT in the new rig. If that combination worked, one could rule out the tank circuits and other parts of the circuit as being the culprits.

Yes, I understand that. GDO of grid is 7210khz with 6l6G installed. Plate tank tunes 6255 to 10__ something, I forget except it more then covers it. I may try the gimmick however I just wanted to see what would happen if I built the circuit similar to my 45 TNT and my 6L6G breadboard deal which both work very well. I spent the day trying several variations of the circuits and am pretty well satisfied while it probably could be made to work it is not a very practical design for this beam power tube. This design of tube does not encourage self oscillatiion like the old pre 29 tubes do. I don't have a lot of formal training so I build it to see what happens as I find that easy.(and fun, truth be known.) What intriqued me was the circuit of a TNT is NOT that different them my breadboard crystal osc. Now I know it isn't the same but the component count on the difference is really quite small So I thought I would whip one up and see. I already have my answer I think. I think I can comfortably leave the experiment here and return to pounding brass on 80M. I have been having a lot of fun with the breadboard rig. As for this experiment I have a metal chassis with a 6l6 or 7AC pattern socket wired in I use it for trying things and it has been through several experiments. It doesn't take much to morph it from on to the other. In its last life it was a hartley with a single control (Dual 365 cap) tuning identical "tuned" coils but not identical sized coils(grid and plate tank) to test an theory I had about coils. It worked fairly well and even did some phone work but testing some of my modulation ideas but it is just a test bench. It has its own on board power supply. Usually cost is zero or nearly so. I might have spent $5 on this adventure. Cheap education. I now understand why crystal rigs became so popular despite their inconvenience. Ease of construction and easy to tune.

From: Roger Kuchera
Topic: 11610 Message: 11610

Gentlemen, During the process of restoring a Emerson "tombstone" radio, I discovered that the speakerfield coil has gone open. The schematic states the resistance is 1800 Ohms. It's been manymoons since I had to deal with a problem like this. These sets used the field coil as the powersupply choke.

I think the short fix is to put a choke in the power supply buss and put a plate-to-loadtransformer in to drive a PM type speaker. Do I disregard the lesser resistance of the newchoke or add a resistor to make up the total resistance? Ideas? Suggestions? Any help wouldbe appreciated. Thanks.

From: Mike Feher
Topic: 11610 Message: 11611

Roger –

I would think that there would already be a plate to load transformer in there to drive the voice coil of the existing speaker, so, a new one is probably not necessary for the PM speaker. As far as the choke resistance, I would be concerned about dynamic regulation of the B+. 1800 ohms does seem high for the field coil, so, it implies that the IR drop across it is acceptable after rectification to generate the proper B+. I would probably experiment with some resistance after the choke (depending on the new choke R) and before the filter cap until you get the voltage the tubes are rated/looking for. 73 – Mike

Roger – I would think that there would already be a plate to load transformer in there to drive the voice coil of the existing speaker, so, a new one is probably not necessary for the PM speaker. As far as the choke resistance, I would be concerned about dynamic regulation of the B+. 1800 ohms does seem high for the field coil, so, it implies that the IR drop across it is acceptable after rectification to generate the proper B+. I would probably experiment with some resistance after the choke (depending on the new choke R) and before the filter cap until you get the voltage the tubes are rated/looking for. 73 – Mike

Subject: [AWA Group] Question re: Speaker field coils Gentlemen, During the process of restoring a Emerson "tombstone" radio, I discovered that the speakerfield coil has gone open. The schematic states the resistance is 1800 Ohms. It's been manymoons since I had to deal with a problem like this. These sets used the field coil as the powersupply choke.

I think the short fix is to put a choke in the power supply buss and put a plate-to-loadtransformer in to drive a PM type speaker. Do I disregard the lesser resistance of the newchoke or add a resistor to make up the total resistance? Ideas? Suggestions? Any help wouldbe appreciated. Thanks. Roger/K1TG

BUT perhaps I spoke too soon! I went back to it after lunch today and discovered a RF choke leaking to ground. These are from a new batch I just bought and this was the first I used them. Plate voltage seemed low to me based on my experience with 6l6s and their cosuins so I went looking for the diagnoser's three friends. "NEW, LOOSE and WARM)New & Warm paid off and I subbed it with the last of my old ones which are a different construction and away she went. It worked best as I first built it with one exception. I changed the grid resistor to get a little more definate action and was handsomely paid back with a strong signal. Key down at the MA meter tune dip 41 ma at 313 volts. I know. Not legal for BK. Don't worry it isnt anyway being a 6l6G. Not a lot of difference to the crystal controlled breadboard rig. Essentially choke and a crystal replaced with GL assembly and a grid coil which is what interested me in trying in the first place. I spent so time optimizing the grid coil after I got it running as dynamic operation is a bit different then grid dip passive testing. I will play with my Antenna link out for a bit till I am happy with it then put it on the air. 40m . Currently best output or sweet spot is at 7018kcs.(It is UGLY though! I am calling it "Frankenstein")

Attachments: 1 described; binary payloads are missing from this source WARC

In the back is the power supply. A 24 volt transformer run on its 220 volt primary giving a net 12 volts fed through a pair of dropping resistors. Why would I use them? I ave two friends in the heating business and they keep giving them to me. The other side is a doubler off the line voltage.
Grid coil is the small one to the left of the tube. larger one is plate tank and the dual BCB variable cap from an AA5 . Both sections are used now . Tank coil is shunt fed and is at ground potential. Tube is an old 6l6G. Underneath is a grid leak (1000 ohms/ 100 pfs) a screen resistor, currently 25K, A parasitic suppressor directly on the plate connection and a RF choke or plate choke if you like. Cathode lead has a 100ohm resistor bypassed by a 01ufd cap. Rig is cathode keyed. Output is two turns of stiff No 12 wire around the tank coil.
Not much too it really. I tried it tonight but no contacts..

Gridleak R is 10,000ohms not 1000 ohms (10k) sorry.
I have been rubbing on this today. Slowly it is becoming a better rig I think. Somewhere I have an unstable capacitor. It wants to drift a couple of Kcs over a few minutes of hard operation. I suspect the 100pf gridleak cap is the culprit. I will dig through my parts bin and see if I can find a better quality one. I could change the value too but for now I just want to see if that is the cause. It is usable though. Just my other VFOs don't do that (except my rice box) I don't know what the end result will be like however if it continues to improve as I rub on it it may be a decent little inexpensive transmitter. Right now it is too early to say for sure. I had it on 40m today (7061khz)Today I built a partition between RF and power supply. It liked that right away.

I have just about hit the end of the road with this project for now. I have learned a lot of interesting things from it. Before I put it away, Lou did you want to try a QSO with me using it ? Seemed to me you mentioned that ealier. My best operational window is approx 7030 to 7060.
don
What did I learn? I learned that a mopa with a gentle running osc would be a better performer from some standpoints however it is usable. Yes a crystal control would work fine if you like being rockbound. I don't!

It OK. I had one of those days too. I gave it a shot at 2 between visitors. We will do it some other time. I have stashed it for now and am working on the bench on a triple double tube AM rig I was working on. (12ah7 osc buffer, 6sn7 audio amp modulator and a 829B final.)
The 6l6 TNT was a good project for me I learned a lot from it. Well worth the effort. So is it a good rig? No not really. It is no better then my 45 TNT for sure and has issues it doesn't. Right church, wrong pew thing. Because I can compare it quickly with the breadboard crystal controlled 6l6 rig since the circuits have only two significant differences I can see why crystal control became quickly popular. I don't like crystal control because I don't like having only one or two frequencies. My next will be a build from the 1940 "Radio Handbook" a 10 watt VFO exciter. Someday of course . Not tomorrow. I have a couple of real good working VFOs based on 6sn7 tube. Very stable with no bad habits. However I would like to see what this handbook design works like. It uses a 6l6 final.

From: dulmagedon@...
Topic: 11627 Message: 11627

I have had some strange things happening in the downstairs shack. Hum problems and lots of electrical noise plus a few phantom failures that made to me no sense. Minor problems but a pain non the less. Lately I got the idea maybe this section of the house, or more specifically this room was wired wrong. So I tested it. neutral was on the wrong side of the outlet. Why I thought if this I don't know it was just a gut feeling something was wrong. So today I fixed it. Already my breadbox transmitter sounds cleaner and some bad hum issues have been significantly improved. Funny changes on signals when I plug in this or that are gone and I am anticipating improved operating conditions. I have lived here since 86 but we didnt use that room for other then storage till I got into the AM and old 29 style rigs. Will be trying later tonight when 80 opens up on 3561 +or - using CW. Probably lose my title now. BWS.

11628. New HB Xmtr Using a 2A5

Yahoo group: AWAGroup (2014 — 2016)
Date: 2015-08-02 21:56:07 UTC
From: Bill Stewart
Topic: 11628 Message: 11628

GA all,
I just made the first QSO with a new HB xmtr. Made it into TN with a 569C,
(on 40 mtrs) report and am all smiles.

The rig is from July 1934 RADIO mag. and is xtal controlled. It uses a 2A5 tube.
I am running at low power for testing...about 250vdc plate and screen voltage...
almost 9 watts input. It worked from the start, with only the tank as a load, but
when I tried the 80m OCF Hertz....no oscillation. I also tried a short wire, which I
use for the ARC-5 on 80m, but about same situation with that and when it did osc
there was a pronounced woop, so the xtal was not wanting to start up. I have now
put a three turn coil around the plug in coil, with one end to gnd and other to the
Hertz....success. Still a slight woop...not bad tho, but haven't played with the
3-turn coil any...just using it around the middle of the plug-in coil. I am using a
Heathkit bench supply, so tone is T9...a more-or-less period supply is planned.
I added a #49 lamp in the xtal lead and it barely glows, so xtal current is low.
It is in the prototype stage now, and after all the tweaking is done I'll rebuild it
for a more neater look. In the next few days I'll do some more tweaking and
may try QRO....maybe 400vdc on the plate....CQ DX!

Ah man I know the thrill! What rock do you have in it? I was playing on 40 today myself. In fact going back down in a few minutes around 7050 if it is open.
On 40 I use a 1 3/4 turn output loop and on 80a 2/1/4 turn output loop. I load into a 4 watt clear Christmas tree bulb for tune up and spotting. Both the 80M and the 40Mgive about the same brightness so I am thinking I am in the ball park.
Anyway I will be listening for you.

Don, I was on 7053 a bit ago. Called CQ for a while, but no dice. Rev Bcn showed numerous hits with good reports, tho. I'll probably hang around 7043 to 7053 during the testing phase.

I had the wrong year on the info...the article is from July 1933 RADIO mag, page 10.

Ah man I know the thrill! What rock do you have in it? I was playing on 40 today myself. In fact going back down in a few minutes around 7050 if it is open.
On 40 I use a 1 3/4 turn output loop and on 80a 2/1/4 turn output loop. I load into a 4 watt clear Christmas tree bulb for tune up and spotting. Both the 80M and the 40Mgive about the same brightness so I am thinking I am in the ball park.
Anyway I will be listening for you.

On 8/2/15 5:56 PM, Bill Stewart cwopr@...m [AWAGroup] wrote:

GA all,
I just made the first QSO with a new HB xmtr. Made it into TN with a 569C,
(on 40 mtrs) report and am all smiles.

The rig is from July 1934 RADIO mag. and is xtal controlled. It uses a 2A5 tube.
I am running at low power for testing...about 250vdc plate and screen voltage...
almost 9 watts input. It worked from the start, with only the tank as a load, but
when I tried the 80m OCF Hertz....no oscillation. I also tried a short wire, which I
use for the ARC-5 on 80m, but about same situation with that and when it did osc
there was a pronounced woop, so the xtal was not wanting to start up. I have now
put a three turn coil around the plug in coil, with one end to gnd and other to the
Hertz....success. Still a slight woop...not bad tho, but haven't played with the
3-turn coil any...just using it around the middle of the plug-in coil. I am using a
Heathkit bench supply, so tone is T9...a more-or-less period supply is planned.
I added a #49 lamp in the xtal lead and it barely glows, so xtal current is low.
It is in the prototype stage now, and after all the tweaking is done I'll rebuild it
for a more neater look. In the next few days I'll do some more tweaking and
may try QRO....maybe 400vdc on the plate....CQ DX!

I gave it a shot for a few minutes just after 8 local time. Tried CQ and your call as well. Lots of QRN but lots of usable signals. I didnt show up on rev beacon but never have anyway. I was using the 6l6 tnt. I had been playing with it last night and got it a bit better but it still walks on freq some when I start sending. Nothing Like it used to but enough to be annoying. I subbed all the caps with different style one by one but it didnt help nor did it change anything. I sent the grid to grid with its resistor rather then risk heating the grid coil but it still does it. I have a couple of suspicions including capacity change inside the tube as it heats up in use. May try a lower value of L on the grid coil and pull it back with some C so the effect will not be as great. Voltage (B plus) is stable so it isn't that. After about 20 minutes it gets a bit better. Anyway i am keeping an ear for you and have saved a 40m Rev Be filter so I can tell when your operating.

Yeah...

The article is in "Radio," not "Radio News," which is a different magazine altogether.

But the link I sent you previously doesn't have ANY issues for 1933, unfortunately. So I can't see the article on Bill's transmitter, either :-(. I should have checked; sorry about that. But the issues that are there have some GREAT articles and projects.

Topic: 11628 Message: 11647

Are you using any solid dielectric caps in the tank ckts, Don? My experiences, while using the solid dielectric caps that were available to me (meaning that they were located in my junkbox), is that they will cause drift problems, when used in a power oscillator ckt. The drift and chirp problem vanished, in my power osc circuits, when such caps were replaced by air dielectric caps. The circulating tank ckt current is quite high, in such ckts, especially if it is a high "C" ckt., which results in enough dielectric heating to cause drift problems, even when good quality caps, such as silvered micas, were used.
I have little personal experience with a tnt, but I have read that the grid ckt resonant freq is rather critical to good performance. With the RF output dissipated in a dummy load, sweep the frequency of your oscillator throughout its range, while observing the plate current. The plate current dip should occur at or slightly below the freq that you plan to use your xmtr on. If the dip occurs elsewhere, adjust the grid tuning until this parameter is realized.

Bill,

Back around 1952 through 1960 or so, my brother and I had a rig on with push-pull 809s. It was a very typical, push-pull triode amplifier. We used National AR-16 series plug-in coils with center links for the grid coils and B&W BVL series coils with a swinging center link for the plate tank. Our neut caps were commercial, a "sleeve inside of a sleeve" coaxial design. We ran about 750 volts and 200 ma to the plates and operated both CW and AM at that level. The one somewhat unusual feature was what we did for grid bias. A single 809 wants 75 volts of bias and 25 ma of grid drive on CW, 32 ma on phone. We used a pair of VR-75 voltage regulator tubes in parallel in series with the bias line with an electrolytic condenser attached across them. When we first applied drive to the amplifier, the grid voltage would go negative until the VR tubes fired, and then the voltage would stabilize at - 75 volts. The capacitor would also charge up to - 75 volts. When the drive was removed the grid current would drop to zero and the VR tubes would go out, but the capacitor would remain charged and it would hold -75 volts of bias on the tubes so that they would not conduct. It was easier than building a bias supply or acquiring bias batteries. The reason we used two VR tubes in parallel is that one VR tube is rated to carry only 40 ma max.

Physically our amp had the grid tank on the left end of the chassis, looking at the front, then a vertical shield with the sockets for the 809s - the tubes were mounted horizontally with the filament wires oriented so that the thin edges were on top and on the bottom and their thick sides were vertical - prevented the filaments from sagging. The plate tank was on the right end of the chassis. The neut caps were mounted horizontally on the shield along side the tubes. We had two meters, one for grid current mounted in the bottom of the chassis and below the grid tank on the left, and one for plate current in the bottom of the chassis and below the plate tank on the right. The filament transformer was also mounted in the bottom of the chassis. We had a steel panel on the front of the chassis.

We ran the amp on all bands, 80 through 10 meters. It worked well. Lots of luck on yours.

I will look into that. I used pumkkin seed caps but tried mica and an orange drop where appropriate. Yes the grid coil can be a difficult part however I have built these before and have some experence tuning it. Found a pretty good method for centering the grid coil in the desired range. I am getting around 4 watts out so I am in the game otherwise I would begetting none or very little when on freq. It just changes freq as it warms up more then my 45 TNT does. I am not running it that hard. My gut instinct on the problem is similar to yours. Something is warming up and changing value. I took a frozen wiener down after lunch(ok. I snuck a frozen wiener down) I was going to look for temp sensitive parts with it but it tasted so good I only got to check a couple.;>) I know it is probably something simple. It is just that the 45 TNT stays put and this one doesn't I will see what else I have for caps.
I was looking or the article Bill built his rig from as I found it interesting and wanted to see what he is running for a circuit and how it compares with my two rockbound rigs.

Usually when one connects a moderate amount of capacitance - say, around 0.5 mfd or greater - across a VR tube you make a relaxation oscillator, which would not be desirable in this application (or any other unless you WANT a relaxation oscillator!). How did you avoid this? Usually, a resistor is placed in series with the VR tube which, if large enough, will stop the tendency to oscillate. Of course, regulation is compromised when this is done. Come to think of it, since the VR-75s are in parallel, you probably already had current-equalizing resistors in series with each tube, which which likely served the function of suppressing the relaxation oscillations as well.

Was a fun build. All from the junk box. Was making 80M RF signal by 3pm. The ceramic trimmer is stolen from a1930s superhet.(#56tubes and such type)
I paralleled the two sections to get enough C but had to pad as well . Didn't have any in the 225pf to 250pf range so piggy backed a couple for now but I am searching my stash for real ones (old). I borrowed the RF choke from my parts bin but will wind one later today on a pencil or something. I didn't put it on areial yet but pumped it into my vintage QRP dummy load. Not too bad really. Not super powerful . Used an 01A for a tube. Is not bothered much by hand and the screw driver tuning of the trimmer isn't as big a pain as I imagined. I don't as i said have enough padding so I am bottomed out at around 3623kcs at the moment. I could add a couple more smaller ones but wish to find the right one instead. I could rewind the coil with some more L but I am not going to. I looks to good so I don't want to mess with it. Right now I am taking a mouse trap down to see if I can make it into a CW key. Anyway I sure enjoyed the build.

Don, I will get copies made and mail them to your QRZ address.
Yep, having fun...making QSOs...just worked KA3P/4 in Fl.
Forty not in vy good shape, but made it for a short contact.
I'll let ya know when copies are on the way. Oh, will also include
copies of a later article for the amp, using a 210.

Thanks Bill, That is most kind. Old designs interest me very much.
I have a few 80M rigs but often wish I had built them for 40M as summertime 80 is not much.
I was on air (3677kcs) with the rat trap rig tonight using the just minted mouse trap key which works very well BTW. No takers but it is working so? In the meantime keep having fun and be sure to tell us of your adventures.

Larry,

1952 when we built that final is a few years back to remember all the details, but yes I think we did throw in a couple of resistors to equalize the current flow through the two VR-75s. The capacitor across them, as I recall, was a 150 volt electrolytic, typical of what you would find as a power supply filter cap in a 5 tube superhet. We did not have any relaxation oscillator problems. That certainly would have shown up on the on-the-air signal! That was a neat rig. It started off on 80 with a BC457 vfo or a 6C4 pierce crystal oscillator, fed into a "bandbox" frequency multiplier, driving a 6146, driving the 809s. The modulator ended up in a pair of 807s in AB2. The bandbox and driver were in one rackmount, panel unit. The final was in a second. The modulator was in a third. The power supply was built into a surplus radar rack power supply, a giant guy with four breaker switches on the front panel. I used to call it "The world's largest 150 watt station." We used an HRO-50 as a receiver. We had it rigged so that we could operate break-in CW, keying the BC457 vfo in the process. It had just a little, distinctive chirp on 15 meters. I still have the HRO, the D-104 mike, and the key from that setup. When we split up the station around 1960, I told my brother that I wanted the HRO and he could have everything else. I think I got the better part of the deal, HI.

I found my stash of 220 pf caps so I am solid to the bottom of 80m. Made a homemade choke and installed it. Put on some more permanent leads and tried it today. No takers but it does seem to be doing a descent job. Was around 3540 to 3546kcs today. I am out tonight so I will have to behave. I rather like this little set.

Probably the two current equalizing resistors killed the tendency to
oscillate.

> That certainly would have shown up on the on-the-air signal!

You bet! You would have been running MCW, ("A2"), and not with a sine wave!

I don't know. There's a lot of HRO-50s out there, but that XMTR was one
of a kind! ;-)

From: Bill Stewart
Topic: 11667 Message: 11667
Attachments: 2 described; binary payloads are missing from this source WARC

The 2A5 is still going strong. Continue to make a few contacts on 40m with good results. I haven't cked all my xtals, but so far the real FT-243s work best. I tried a couple of 'stuffed' FT-243 holders and they drifted. But xtal current is still at a low value, according to the #49 in the xtal lead. I also found that the 3 turn antenna link works best around the middle of the tank coil. At 250vdc, about 8-9 watts input....and abt 75 ma of RF into the antenna, what ever that means. Tinkering and tweaking is still in progress. It's a prototype so changes will be forthcoming.

Attached are a couple of pix. The LH variable cond. is not being used so, at the moment, it is a single control xmtr.

I continue to work on this little rig. I really like how it performs. Did some measurements today. Inputs. Plate voltage keydown loaded into a long wire antenna, 232 volts and 34 ma. don VE3LYX

11669. 6L6 TNT morphs into a 6SN7 TNT

Yahoo group: AWAGroup (2014 — 2016)
Date: 2015-08-08 11:08:25 UTC
From: dulmagedon@...
Topic: 11669 Message: 11669

Since the rat trap is finished and on the air I went back to the TNT. First I rewired it for a BBD twin triode. Installed a 6SN7 as a parallel pair and fired it up. Works not too bad. Rewound the grid coil with heavier wire(26 instead of 30) and centred it on freq with the new tube. Later I tried a 6BL7 with success. I am still playing with it but I must say the hartley as in the rat trap is a better rig so far.
Been listening and watching (revbec) for Bill. I don't show on Revbec even when in QSO so I must be out of skimmer normal range. Anyone else wanna come out and play I am working around 3547 to 3567 on 80M with the rattrp and 7040 to 7080 with the TNT. When I get bored I pop the breadboard on at usually 3561.

It has been a busy day. I spent it cleaning up both transmitters. The Rat Trap came out particularly well. I added the knurled knobs for attaching power. Also a tuning handle for the tuning capacitor on one side only. The other side is for calibration. Hopefully it does not need adjustment. The mousetrap key works really well. Why I don't know. It just has a good feel and is easy to use. mounted on the key is a bulb socket with a bulb. All B neg which is what is keyed here anyway must pass through the bulb and it can be used to monitor input power simply by watching its brightness. Besides every transmitter needs some flashing lights! Operating around 3540 to 3550kcs

Today I put on a permanent octal power cable and switched it over to AC heater supply. With the clip leads gone things settled down. After about a half hour the 201A I was using gets stubborn. So I dug out my 45s (go big or go home!) When 45s get weak you can squeeze them for a while if you are careful by pushing the heater voltage. Eventually they will die but since they are no good anyway it really doesn't matter. I wish the 45 was still available new. I had 2 that needed that. This power supply has a 1920s heater rheo built in so I can go from zero to 6.3 easily. I tested all three. One 45 is still full output on 2.5 heater volts so I popped it in. Man did that wake things up! My B- lamp indicator lit on keying so I measured the input current . 68 ma. B voltage sags on this supply but input is still well above 11 watts. The FS meter I use to monitor all shack activity was banging its needle on the dahs. I got one reply but noise level was too high for a QSO.
don VE3LYX
Just for comparison I fired up the breadboard crystal control rig on 3561. Got an instant reply. I am liking that rig.

11673. Anyone up for a 80M sked or test?

I have the power up to decent levels I think and the set (RAT TRAP)is fairly well behaved. It has a bit of a whoop to it but not bad so it should be easy to pick out. I am tuned up on 3546kcs currently +or- and can move around freely in that section of the band. I am running just under 2 watts input so if the band is good there is hope. It will be not open soon until evening so that may be best.

Don, I've been pretty active the last few days with the 2A5 on 40m.
I cked the RBN for you, but no entries. I've been hanging around
7036 or so, depending on QRM on the xtal freq. I've got some xtals
that do the yoop-de-yoop, but can help that a tad, by tuning the tank
cap. The 7036 is my best performer and can get the most output from
it before it stops oscillating.

Have never tried a trippler p/s. For the tube stuff, I usually use the
standard full wave. Will probably build up something for the 2A5 using
a 80. I probably won't run over 400vdc B+. Now I'm using a Heath
bench supply. Oh, I see some 2A5s on eBay that are not too pricey
but other tubes, as mentioned, should work fine.

Yep, some of the modern-rig ops don't know what to think if they hear
a sig that's not up to modern day standards. When I'm chirping or yooping
I sometimes get a report that my battery is weak...hi. I stick to CW so no
AM in the future. I generally work 160 thru 40 and a little 20 sometimes.
Antennas are wire...no beams, so don't do any DXing anymore.

Ok Don, keep sniffing those rosin fumes....73 de Bill K4JYS

I'm afraid that's not entirely accurate, Bill. :-) I distinctly remember talking to you on AM during an AWA "30s night," which morphed into the AWA AM QSO Party. I was using a homebrew grid-modulated 807 rig at about 7W carrier, and my FB-7. Do you recall? Probably over 10 years ago.

Oh I have been a busy boy. Rosin fumes were again rising. Today the 6l6TNT which became a parralel pair 12sn7 TNT morphed onto a Mopa with a hartley PTO and the original tank as a final on the other half of the 12sn7. I fired it up on the dummy and it was at 6090kcs, A minor adjustment of the slug in the coil and it was on 7043 kcs. Final tank tuned in nicely. Always nervous when stuff works first go.
As for RBN. I have never seen me there , not once ever even when on my TS830S. I will listen for you on 7036kcs. The Big Dawg has a good bark so it should work. We shall see. My brother from Ottawa was here just now. He is a E tech for our old company (now Nemko) so I took him down in the shack as it is his field of work. He liked the 211 rig and the tank radios. Said he should take a photo but didn't. We tried several including some of my primitive AM rigs.
Great hobby!

Ya got me Larry. Used to do a little AM work. I used the Viking 2 and AF-67 mostly. But haven't had them on AM in a good while. I don't recall that QSO.. that would be taxing my old brain too much. Ummm, that might be a good winter project, to get back on AM. 73, Bill K4JYS ----- Original Message ----- From: "Larry Szendrei ne1s@... I enjoy AM. I am no good at the old buzzard long talks but I enjoy the mode. The Old military rigs (No 19 WS, ARC5s) have worked the best for me. I have a DX60B set up but am not in love with it. I guess I feel it could have been a much better radio with a bit of thought. I really love the homebrew AM stuff and have a transceiver I have been beating on for years that I am finally happy with. It isn't high power but it works well. 6v6 screen mod, carbon mic circuit. And the TNT on AM is a blast as it will reach as far as the DX60B anyway. I only use it on willing victims though. (folks with similar interests in primative AM methods. Don't call CQ with it. I use it if it comes up in conversation as sometimes they ask to hear it). CW though is always fun and I am struggling to get back to the point I am more comfortable with it. I neglected it too long and am paying a price for that even though I used to be pretty decent at it. Now I seem to panic a bit. So in the shack I often read the mail now in CW. I find a lot of VE3 folks saying they don't show up on the RBN ever. No skimmers in our range I suspect.
As to the tripler PSU I also moved keying to the power supply keying the suedo cathode network and then just feeding the two heater wires and B+. I think I may rework my other supplys the same. I like it. Only three wires to hook up. Cleaner neater and it seems to me to work better. Anyway I am monitoring 7036 as a rule now.
Hope to hear you Bill but so far no joy. There was a KK4 on last night for quite a bit and a A0 . It will happen. Just need the right conditions.
Haven't heard Larry on in a while either come to think of it. He must be spending too much time driving the Falcon.

I heard you just a few minutes back on or about 7026.6. Not real strong but copyable on the pekas. it dint last only a few minutes then you was gone! you were working another k something. I gave it a shot with the PTO Mopa while I scrambled to tune the Big hartley donw there. I gave it a shot and was on freq but the band was gone. I saw you come up on RBN so ran down to try.
Nice rig! Signal was not heavy but on peaks(QSB) was very good Sounded nice too. I would give you a 449 however I was excited so you can probably upgrade that one. Any problems were strickly conditions.

OUTSTANDING! Don...yep, that was me. Tnx for the report. The band has been funky for a while now, and the QSB goes deep and sigs go into the mud. When condx settle down, maybe we can try a sked. I was using a woopie xtal so had to reduce power until the xtal would start sharply and not lag the key closure. For some reason I get a lot of strong RBN reports from VE2WU...sometimes over 20db...must have a lobe in his general direction. Tnx agn OM...73, Bill K4JYS

Hi Guys,

Just wanted to share with you all the recent passing of Mike (VE3DKW)...

He was a fairly regular participant in the 1929 QSO Parties of yore, an enthusiastic OT radio fan, and once won the Linc Cundall contest for best overall score.

We lose another one to the ranks of the Silent Keys...

~73~ de Eddy VE3CUI - VE3XZ

SHERBA, MICHAEL PETER -

(Retired technician from Bell Canada; life member of the Amateur Radio Club)

DURHAM WEBSITE [1] Peacefully, with his family at his side, on Monday, August 3rd, 2015. Mike, in his 85th year.

Beloved husband of the late Vera. Loving father of Kathleen Sherba, Joanne Sherba-Cordy, Michael Sherba and Lynda Motschenbacher. Dear grandfather of Nikkolai Cordy, Lucas Cordy and Melissa Motschenbacher.

At Mike's request, cremation will occur with a private family gathering to take place at a later date.

In lieu of flowers, donations in memory of Mike to the Alzheimer Society of Durham or to the Canadian Cancer Society may be made through MCINTOSH-ANDERSON-KELLAM FUNERAL HOME [2] LTD., 152 King St. E., Oshawa (905-433-5558).

Online condolences may be shared at MAKFUNERALHOME.COM [3].

We, the family, are thankful to Margery McCoy that she was able to give our Dad love and companionship. Margery is a very special lady who held an important place in our Dad's life.

We are forever grateful to those who took special care of him: Thank you for the compassion from Dr. Dion and the Palliative Green Team, St. Elizabeth's Home Health Care (especially the support from Elizabeth 'The Saint' Stacy), for the help from ParaMed Home Health Services (LeAnne, Elisso, Osseri, Jennifer) and to all of the other PSWs who came with a smile on their faces to make our Dad more comfortable.

A special thank you to Johnny Bastas for making sure that our Dad was always looking sharp for the ladies; and thank you to Mark Bendzsa for always giving our Dad VIP status.

Our Dad was a man who taught us to love family, cherish the moments and respect each other. He will forever hold a place in our hearts.

I haven't transmitted on 40M AM for quite a while. I've listened up in the 7285-7295 region, and have heard very little activity, so haven't jumped in. Plus I'm busy with summertime projects. I have been on 75M AM just a bit, usually once or twice a week in the mornings.

I don't leave the homestead too often, but I have had the Falcon on the road to run an errand about every other week. I'll be taking it to the Windsor, ME hamfest in a couple of weeks, and also to NearFest in October.

73,
-Larry/NE1S

P.S - Lou, did you make it to the Convention?

What year is the Falcon Larry?
I drive a 63 Dodge when I am not playing with tubes.
I haven't been on AM for awhile either. Used to talk with VE6PG on 3725 every day but he is working more daytimes now so misses that window. He was very helpful in getting me up and running on AM and was always up for a test. Many of which were successful. He lives not far from Lou. maybe 50 miles away. These CW rigs are fun though. The 6l6 TNT experiment which morphed itself into a 12sn7 hartley mopa appears to be a decent set. I used a slug tuned ceramic coil form for the hartley coil and brought the adjusting screw out the front with the coil under the metal chassis. I put a fixed cap (150pf) accross the hartley coil to bring it in range but tune freq only with the slug . These coil forms have good metal hex screws for adjusting. I used 16 turns of litz centre tapped for that coil. The PA side of the dual triode is the same coil and vari cap I had when it was a 6l6 tnt. It has an almost 2 turn loop out one end grounded around its 1 1/4 inch coil wound with 14 turns of #12 insulated wire (from house wiring) The supply which is on it is a discarded 24 volt transformer from the heating industry .I used the 220 volt primary so I have 12 volts out for the filament.. The B+ comes from a doubler circuit built from the same feed. Anyway I am hoping to work Bill, 2a5 with this one.(and the Big Dawg) It hasn't huge power but I think enough for good conditions. Being able to tune it anywhere on 40M is nice and it appears to me to be very stable. It is small and light so if it works on air it will be fun. BTW nice to see activity like Bills.

For Don, VE3LYX,

If you are unhappy with the AM performance of your DX-60, have a look at http://arizona-am.net/index.html and click on K3YAZ. Frank Cathell has souped up his DX-60 to use a pair of 6146s, and he has improved the modulation as well. Both ideas are illustrated with pictures and schematics on his page. I used his modulator idea on my Knight T-150A which already has two 6146s and I'm told it made things better. I've worked Frank's DX-60 and it sounds quite good.

I have looked into that too but I wasn't complaining about the AM performance. I just don't like the radio period.
No 1 only crystal control. So you have to buy or build a VFO. I did the later. Also crystals are inside at the back so if you want to change crystals you have to pull the stupid thing down off the shelf to change them. What would have been wrong with a crystal socket out front?
You already covered the power thing. Why only one 6146? The load control is a joke. Sort of works. The calibration means little and is merely a guide. The VFO is powered when the rig is not keyed (key or mike) so you can hear the osc in the rx unless you switch VFO off. I know you can install a relay and probably the Heath VFO already has it but why. Such a simple thing but not done.
If it were something I was going to keep I would jerk the crystals and their holders , build the VFO right there and run a shaft for its variable cap where the crystal selector now is. I would drill and blast for two 6146s and I would put more stomp in the speech amp. I would junk the lovely plastic meter and install something that looked like it belong on a RADIO. I would also repaint it a colour I can see. I am severely colour blind and can't tell if it is green or blue or some other hue.
I guess I just don't like it even if it has been a help to me getting on AM. Since I got the tank radios , No 19 WS I have only had the DX60B on air once. I would rather use 6 watts of RADIO then something that looks like a Tonka toy despite its extra power. Now if any of you have a DX60 please don't be offended. This is just me. My heritage may be poking through my square head. So feel free to run the dust cloth over your DX60 saying "there there" soothingly. And you can think bad thoughts of me the rest of the day. Hopefully you will forgive me tomorrow.

Whatever works. But all the wisdom and experience of the past argues for the high-C/low-L tank circuit in the oscillator for best frequency stability, and higher L/lower C in the amplifier in the interest of greater plate efficiency and output.

Gentlemen, I recently constructed and tested the "WA3TFS Audio Notch Filter and Clipper" from the Augustissue of QST. It is a commendable adjunct to a vintage RX.

There is not evidence of ringing. My only negative comment would be that when using "hi-fi"phones there is a slight bit of 120 cycle hum. I believe it may be residual from my RME-69. I havefound that coupling it to my RME-69/BC-453 it makes a very selective combination.

Roger/K1TG

I am not familiar with that article, as I am no longer a ARRL member and thus no longer receive QST.

However, I might add that a Softrock Lite II* built for 455 KHz, coupled to your RCVR's 1st IF and fed into the soundcard of a computer running the appropriate (free) software makes a formidable modern-day "Q5-er" with capabilities that were unheard of just 15 years ago. I use one with my SX-28; it's awesome.

* available from www.fivedash.com as a kit, I had mine delivered to my door for under $30 total. Has some tiny surface-mount components, and since I'm such a klutz I could bridge the pins on a miniature tube socket, I enlisted help putting mine together. No connection with fivedash.com or the Softrock kits other than being a satisfied customer, etc.

Hi Larry, This particular filter is very basic and works at audio frequencies. Needless to say, it does notperform like a digital IF filter. It's redeeming virtues are that it is simple, cheap and it works well.

I installed a lo-Z to hi-Z transformer so that I work into vintage cans. The 120 cycle hum wasgone on my Brandes Superior headset.

However, I might add that a Softrock Lite II* built for 455 KHz, coupled to your RCVR's 1st IF and fed into the soundcard of a computer running the appropriate (free) software makes a formidable modern-day "Q5-er" with capabilities that were unheard of just 15 years ago. I use one with my SX-28; it's awesome.

* available from www.fivedash.com as a kit, I had mine delivered to my door for under $30 total. Has some tiny surface-mount components, and since I'm such a klutz I could bridge the pins on a miniature tube socket, I enlisted help putting mine together. No connection with fivedash.com or the Softrock kits other than being a satisfied customer, etc.

Did someone say Slant six. That is what I was driving when fractured my spine. My Slant six dragster, now retired. (You tube Senior Dragster , also SR Dragster))
I hadn't thought much about that Larry It was a junk box build and I knew the coil would be on freq if tuned by a normal commonly used variable capacitor. I had the 150pf in the box so whipped it on soldered it in circuit with the tube in place and checked it with the GDO. Was in spec so I fired it up. It came on line at 6090 so a 3/4 turn in got me in band. Next time I will try a 50 pf and more turns. I guess I was thinking 365pf would be a lot. It covers the whole band anyway even to the AM window. Tunes nicely. Output isn't super but a couple of watts at its best spot. Should do on a good day or with someone not too far away but in range. It has an on board PSU shielded from the RF section. It has no bad habits. I wanted the osc section very lightly loaded which always improves stability and then pumped that through the next triode section to get some power. It would do nicely as a VFO crystal substitute as well. My brother bought me a whole box of Weston meters for my birthday but he just brought them in last weekend. I bored a hole today and used the 300 mico Amp with a shunt to get the meter in range (You know. workable range , not calibrated range) on the plate current. Dips nicely on tune.
The slug tuning or PTO is a real boon to the rig. Really really works nicely. I may be addicted. I have two other radios (solid state) that I used it on before this one. No hand capacity effects whatever. Solid as a rock other then tube warm up. After about 7 minutes it is pretty well over and away you go. Of course I never wait that long. ;>). The XYL nicknamed this one Cyclops.

I think we're talking about the oscillator tank and not the PA tank,
right? If so, that would be the wrong direction. I would start by
doubling the capacitance, and halving the inductance. I woult use
heftier wire, for half of a 12SN7 at least 16 gauge, and larger wouldn't
hurt. Litz wire offers no advantage at these frequencies, and won't be
able to handle the RF current with a proper high-C, low-L tank circuit.
Save the Litz wire for the low-frequency regens and crystal sets -
that's where it'll shine.

50pF is probably about right for the PA tank (guessing from experience
without "doing the math.")

Hey, if it works who am I to argue? But perhaps it could work even better.

Calibration is nice, but getting the shunt correct for a calibrated
scale is often not possible with the resistors on hand. Been there, done
that. For your purposes, you just want to be able to see the qualitative
effect on dipping and loading the PA. If you want to get an idea of the

scale just stick a VOM on an ammeter scale in series.

That's cool. It wouldn't have occurred to me to use a slug-tuned coil in
this application. I'll have to remember that.

Speaking of Cyclops, there was a single-tube regen published in the
1940s called that. It used a 6E5 magic eye tube as its regenerative
detector, which provided a visual indication of when the detector was
oscillating.

There's your next project, Don!

I am no litz wire fan. It just happened to be in the box when I decided to wind the coil. I saved it from a 1920s radio I dismantled. Normally I use light solid core hook up wire but for a 40m with these slug tuned deal I cant get enough L with it. Anyway it turned out to be a nice little CW rig so I am happy. I have a tuning eye tube here I used to build a modulation monitor of sorts. It wasn't practical but worked to the extent you could see the change and if you pushed it too hard the lines would meet. I can see it becoming a tube for a regen. Good name for such a rig.

I read your build with great interest. That is not an easy build so you are to be commended. One thing though was you comment regens cannot be compared with modern receivers. I will say it again. A good working regen will put any modern receiver to shame as far as what it can hear. No 1 problem is too much antenna and too much gain. A few feet of wire or a small loop three turns on a ten inch form will get you the world and any QSo you might wish. They are not easy to run but once one gets used to the radio and its habits they are a very very effective piece. I would run it for awhile before I said anything. You may be pleasantly surprised. Here in regen central (currently 8 operating and one in the hospital) I try to use them for QSOs as well. The classic twinplex is so far far and away the best I have built and used. I have it in the 6sn7 version. I compare it against my TS830S and it wins hands down. It hears stuff I can't even find on the Kenwood.
Anyway you executed this nicely. Congrats and thanks for the link. You do nice work!

11708. Big 1 1/2 volt battery

Yahoo group: AWAGroup (2014 — 2016)
Date: 2015-08-21 15:58:41 UTC
From: dulmagedon@...
Topic: 11708 Message: 11708

Thank to Steve and his project I decided to drag out one of my regens. This one currently has a pair of 26 tubes in it which are 1 1/2 volt heaters . I found a single D cell didn,t have enough to bring them up to temp and two could just barely do it. I decided what I needed was one of those big ol tall 1 1/2 volts we used to buy back in the day but they are gone . However in my mispent youth I had taken apart a few batteries and new that 6 volt lantern cells have normal batteries inside wired in series so the 4 1 1/2 make 6 volts. So I went to town and bought a lantern battery. Alkalines were on sale so that is what I came home with. I took the battery apart by bending the bottom flange out with a pair of sidecutters I disassembled it and found four normal length alki d cells inside and a card board stuffer. I stood them all upright. Neg bottoms and positive tops. I soldered the bottom contacts together with a hank of wire and fed it up the side of the batteries. I tinned the positive bump on top and connected the with some wire. I put the stuff on top then soldered the wires to the spring contact at the top + to the + one and - to -. I assembled the battery and as neatly as possible refolded the edge. Being the bottom it isn't visible anyway but I tried to make it decent. checked and sure enough i now had a large 1 1/2 volt battery. I grabbed the twin 26 regen and hooked it up to this new heater supply nd hooked up the B + (multiple 9 volts.) clipped on the antenna , rimmed the antenna coupling and tuned for a station. Surpisingly I found a Cw station banging away and up band a bit a SSB conversation going on. I listened to the SSB for a bit and then remembered my bold statement this morning about regens ability to hear. I brought the regen control just up into oscilation and searched for it on the HR 10 receiver which is on a beveridge and does well in poor conditions. I found where I was tuned to quickly and killed the regens osc and looked for the SSb sig, could not find it anywhere and yet this ol regen could hear it. I mean I could understand what they were saying it wasn't just a somethings there thing.So I switched to the DX 390 RadioShack receiver which is a handy addition to the shack. I could not find the SSB either but could still read it on the regen. And this isn't my good regen. it is a so so one so i stand by what i said once again. Having confirmed it again for probably the 20th time. Very senstive radios although not easy to run. And now I have a big 1 1/2 volt battery. All I guess thanks to Steve and his adventure.

Very, very nice, Steve! With we had a Metal Supermarket or the
equivalent around here. I've long lusted after that particular project,
but the metalwork (materials, tools, and skill level) have prevented my
from trying to reproduce it - so far.

I did find one error you may want to correct. You wrote "Grammer also
gave the builder a choice of using 2.5V or 6.3V tubes and I chose the
six-volt variety ... 78's (RF and Detector) and a 58 (Audio)".
Since the 58 is the 2.5V heater analog of the 78, and is a pentode, I
think you meant either 76 or 37.

One question: did you make that recording with your hand on or off the
tuning? ;-)

My summer radio project has been at the other end of the time-domain
spectrum - building a Softrock Ensemble II SDR receiver kit.

Have you tried lowes or home despot? They do not have the selection of metals that MS has, but...

Another avenue to try is to look for a metal fabricator. Maybe they will sell you small pieces.

Thanks all for your nice comments!

Don - the experience you have had, comparing sensitivity with modern radios, has not been duplicated here. Both of my regens (Paraset and this one) are very sensitive up to around 10MHz when comparing them with my modern HF radios. Although the 1930's front-end tubes have a high noise figure, it is still not high enough that normal band / atmospheric noise up to at least 40m and slightly above, can overcome the tube noise. Even today, in daylight, on my very RF-quiet island, the Grammer receiver can detect atmospheric / band noise on 7MHz. so I think I can safely say that on 40m and below, the sensitivity of these radios is 'more than enough'. That's about the only area that these things can compete with anything modern...selectivity, stability, frequency calibration etc cannot be equalled at all. For a 1930's radio, this one is really very stable and sensitive and would certainly have been a wonderful addition to most shacks of the day.

Bob - unfortunately I don't have any dial-stringing info for this dial. I have asked around and if I get any responses, will pass them to you. I can (let me know) if you wish, send you a photo of what it looks like from the outside but most of the complicated stuff is all enclosed inside the drum. I studied it earlier and just shook my head as I could see no way of opening it without having it all 'jump' apart on me...it's all very tightly wound.

Roger - the 1/4" brass bar stock was bought at the Metal Supermarket. They will also do mail orders if you have these in the U.S.

Larry - thanks for picking-up the error on the webpage. I will change that this morning! The one great thing with this receiver, likely because of all of the shielding, is that there is no hand-effect whatsoever. Once the RF stage has been peaked (preselector), the regen level set and the AF gain set, it is strictly a one-knob radio. It will easilly tune through the entire 40m band with no adjustment needed and several MHz higher / lower, just by re-peaking the RF stage. The regen setting holds throughout the entire range. The way the coils are wound, along with the small variable, spreads 40m over more than half of the drum dial.

Gentlemen, As I recall Fred Sutter built one of his mini-rigs as a regen and he made a point of the factthat most regens suffer from too much antenna. I believe he used an old car antenna on hisregen.

Alas! We had a Metals Supermarket locally until state and local taxes drove the shop outof business. I may try them via the net. Thanks for the skinny.

I believe "GG" would be pleased to see your unit.

Well I wouldn't dispute any of that. Sensitivity is their strong point and they are not great at above 10mcs. Selectivity is acceptable for me even in crowded conditions because the note tone between signals lets me follow my Qso and ignore the rest. I have a couple that are real stable and not bothered by hand capacity but my best for sensitivity also have that annoying trait. I have learned to deal with it. I run most of mine on batteries so for low signal work there is almost no noise. Sig to noise is always good when noise is at a minimum. What we sometimes think is atmospheric sometimes isn't. It is downright spooky how quiet conditions are on battery compared with a PSU, even a good PSU. Anyway nice job. I knew I had seen the circuit before. A modified version of the same radio is in my 1939 Hammarlund Shortwave Manual. I dug it out this morning and compared pictures then read the whole article. It says the original circuit appeared in the tenth edition of the ARRL handbook several years before. Changes were minor. Must be a pretty good radio to still be recommended that many years later. Enjoy.

Take a look at the National 1-10 and the HFS. Regens that went real high in frequency. There are a lot of pre-WWII military regens also that went pretty high. My Ocean Hopper worked fine above 10 MHZ. However, about 1962 I found transistors and I built a 10 meter regen using a Philco Surface Barrier transistor. I remember with that tiny set, on a piece of vector board, out in my back yard on LI, I could hear the world on 10 meters with no problem using a short wire. Admittedly, 10 meters then was really hot. 73 – Mike .

> the fact that most regens suffer from too much antenna.

I did notice this behavior in my Paraset regen when first built. It suffered from tunable hum and was going into regen mode with an audible 'click'. The original 100pF was slowly reduced until at 10pf the tunable hum had vanished and it also went into regen smoothly with no click or thump...I was surprised that both of these were the result of overcoupling.

The new Grammer is just the opposite when it comes to the antenna, probably because of the RF stage nicely isolating the detector...I had first tested it with a 50' piece of coax going outdoors to one of my LF antenna's loading coils, in effect, a random length of wire. When I put the full-sized 40m coaxial-fed antenna (half-sloper) on it, I couldn't believe the difference...it was like a totally different receiver.

Thanks Don...yes, I have seen this and was also surprised at the publication date. I would have thought the receiver to be getting a little long-in-the-tooth by then as superhets, or some form of them, were probably the norm in most shacks by 1940. I have also been told that the Grammer regen was so popular in its day that Hammarlund actually manufactured and sold pre-wound coils for it! I'd love to get my hands on some of those.

Well it sounds like you are enjoying it. Yes, I have a RF fronted regen here too. Built from the Powerhouse Design as they called it. It has very different chracteristics from a normal unfronted regen. I am still not sure if I like it or not. However you got me back in regen mode and I have been rubbing on this old twin 26 tube regen this afternoon. Changing a few things I should have done before. Finally I fired it up again with a set of 9 volts that are sagging but still enough for it to work. I found a roaring 20s music show on 49M and was listening away while I was putting my tools away. It seemed appropriate when the music finished and the announcer said "That record was released Nov 14 1927." As could have been the radio I thought!

The 1-10 is a superregen. and the HFS is a superhet. (I have one of each. In fact the HFS I have came from the top of Mt. Washington - I was told by the gentleman who gave it to me that it had been used in some capacity in Major Armstrong's Yankee Network.)

Yeah - missed those days, unfortunately. I was just 5 years old in '62. It was a year or 2 later when I pulled my first radio out of a trashcan, and I was using a soldering iron about a year after that.

Well generally around 10 meters which in the old books is VHF beginning they would go to supergennys. My transceivers regen section I built has coils for 15 meters and functions there.10 M would be workable but it is about the practical limit. I have a 2 M super genny aka benton harbor lunch box or a Twoer and they made the same set as a six er and a ten er . I have a ten meter regen here built in a card file box and it works but I am not pleased with the whole deal so I set it aside for now. It is an AM rig. To enjoy a regen it has to work everytime without a lot of fiddling. Not all do that. That is how certain designs got popular. They were easy to run and always worked. Some folks can squeeze a regen to its limits and some cant get a single signal on the same set. I watch and check antenna coupling a lot on the one I was using today. It is sensitive there. The twinplex for me has been the easiest of the old designs. It always works and works well with no baloney or fiddling. I am confining this to tube regens. I do have several of the other variety but they dont belong here.

11723. Classic Exchange this September

Yahoo group: AWAGroup (2014 — 2016)
Date: 2015-08-22 17:23:16 UTC
From: JAMES HANLON
Topic: 11723 Message: 11723

This is a reminder to all of you good folks that the Classic Exchange will be running again this September. In particular, the CW portion of the CX is set for Sunday, September 20 from 9 am EST to 3 am EST on Monday, September 21 AND on Tuesday, September 22 from 9 am EST to 3 am EST on Wednesday, September 23. The Tuesday-Wednesday is a new time slot that has just been added to the traditional CX time on Sunday.

The Phone portion of the CX is set for Sunday, September 27 from 9 am EST to 3 am EST on Monday, September 28 AND on Tuesday, September 29 from 9 am EST to 3 am EST on Wednesday, September 30. The Phone portion is open to all modes, AM, FM and SSB, and there are separate frequencies recommended for each mode.

In case you haven't heard of the CX, here's a short description from the web page at www.classicexchange.org . You can find a lot more information on the CX such as frequencies, scoring, the exchange, reports, and the CX Newsletter at that site. Click on SEPTEMBER 2015 CX ANNOUNCEMENT for details about the upcoming run.

"The CX is a no-pressure contest celebrating the older commercial and homebrew equipment that was the pride and joy of ham shacks many decades ago. The object is to encourage restoration, operation and enjoyment of this older Classic equipment.

However, you need not operate a Classic rig to participate in the CX. YOU MAY USE ANY RIG in the contest although new gear is a distinct scoring disadvantage.

You can still work the "great ones" with modern equipment.

There are new Bonus Scores for using the same model rigs as your Novice station and for using a Hallicrafters receiver with a two number identifier, e.g. S-38, SX-99 and for using a World Radio Lab (WRL) transmitter, e.g. Globe Scout 65."

I think it would be a good idea for those of us who are running our low power 1929 or WW2 transmitters on AM to set up a time and frequency schedule for participation in the CX. That would help everyone, both the QRP/OT folks and the "regular" AM ops to get together, and it might result in some interesting DX contacts for the QRP/OT guys. What say?

Jim Hanlon, W8KGI

11725. Bands 40M & 80M Were Open Tonight

Yahoo group: AWAGroup (2014 — 2016)
Date: 2015-08-23 03:12:25 UTC
From: dulmagedon@...
Topic: 11725 Message: 11725

I went down to the shack about 7 30pm my time. By dark there was a lot of activity. Both on 40M and 80M. I tried a few calls with several rigs but too crowded for low power tonight. The Rat Trap still hasn't a QSO even though as of today it is putting out 5 watts into the antenna. I think the whoop whoop makes normal operators nervous. I had the 211 Hartley on tonight and it surprised me it didn't make a connection as I have had some success with it recently. I had the breadboard station on for a bit. Then I switched on the No 19 wireless. There was a QSO on 7290kcs. I have worked him twice recently so I let him enjoy this one. I switched to 80M and found some there too. I popped the big long wire onto the ARC BC 454 rx and powered it up. Checked out the band. That Rx seemed to be working well tonight. I thought about firing up the 80M ARC 5 but had stolen the modulators tubes for the breadboard project. Anyway it has been a long time since I heard this much activity on the bands. Jim's post reminded me to get everything working and double checked. Nice to see the bands coming around .

11726. Pierson-Delane PR-15

Yahoo group: AWAGroup (2014 — 2016)
Date: 2015-08-23 19:27:17 UTC
From: Larry Szendrei
Topic: 11726 Message: 11726
Attachments: 2 described; binary payloads are missing from this source WARC

Yesterday a Pierson-Delane PR-15 followed me home from a meet. (It was a package deal with another radio - a Breting 12 restoration project - that I bought.) Patterson originally produced this receiver before it was manufactured by Peirson-Delane.

It appears to be an incomplete restoration, with a freshly-painted cabinet. It is missing the dial glass, and the silkscreened metal "mask" that hides most of the tuning dial mechanism. I would love to find one in order to complete the restoration of this beauty, so any suggestions would be welcome.

There's a puzzle, though. All the PR-15 photos I've found in books, advertisements, or online show an oval dial opening/escutcheon, as in the attached file PR-15_2. This is rectangular on mine, shown in PR-15_1. Can anyone shed any light on this?

Thanks for any leads on the missing part, and the escutcheon mystery.

11729. Another Regen 56 and 58 tubes

Yahoo group: AWAGroup (2014 — 2016)
Date: 2015-08-26 01:48:14 UTC
From: dulmagedon@...
Topic: 11729 Message: 11729

Spurred on my Steve's recent build I remembered I had some of those ancient tubes around. One was in a regen/transceiver I built which had recently become a parts source as I no longer use it. I stripped it down to its base and sockets and started over. Nothing exotic just a typical Hartley regen which is little more then a osc struggling to oscillate staving for fuel (Plate volts)while phones monitor the load. I used the 58 as an audio amp. Started soldering about 9 and had a signal in the phones before lunch. Spent the afternoon making a new front panel and trying different values to see if It could be improved. It is centered around 30M but ventures into SWL zones as well. Not a world beater or anything. Just a lil ol regen that would have been right at home in somebody's shack back in the dirty thirties. Kind of a fun build on a cloudy day. I want to try a passive RF stage ahead of the unit just to see what happens. Never spent much time on 30M . Anything vintage happen there?

A few war wounds from the previous build but here it is. ALSO today I rebuilt the PS I did for my Wireless #19 today. Maintaining full voltage on transmit however sounds a bit hummy on the monitor. I built the economy supply from the 80 ARRL book (The blue one 82?) but the design has been in several of their books. I had thought because if that it should be ok. What are the tricks? Or is my monitor too close to make a decent judgement. (same room) PSU hum is my weak spot. I would like to change that.

I am starting on a project I call "Eddystone 2015". It will be a replica of the WW2 vintage Eddystone "All-World Two" from Great Britain. This set played an important part in intercepting enemy radio signals by English hams who were "Volunteer Interceptors". A set worthy of copying except for a few minor details like parts that are non-existent, at least on this side of the pond. I will have to make substitutions as needed for parts such as the detented bandset variable capacitor, the "Mullard" tubes (I'll use a #34 and a #33) and some capacitors. It will be electrically as similar as possible to the original and the physical resemblance will be strong.

I ran through the 2.5 volt deal here as well . Both with the 45 tubes I use and the new regen which is a pair of 2.5s and seriesed for 5 volts so I cheated however I use a HD 6.3 winding and a old radio heater rheo to keep it and the 2.5v 45 transmitters on voltage. With the 45 tube it is surprising how much it takes to keep it at 2.5. The 56 58 regen is quickly becoming my favourite. It is a hartley so a lot of the regen issues with an Armstrong are non existent. It is smooth , almost on perceptable going into regen. It hears well. Hum even on AC power is not an obstacle although still quite noticeable. I made some real inroads into making it manageable today. It is silent that way on battery heater power. Hope to make a qso using It soon. it is a 40 m only regen.

There are two of them; one for 7 pin sockets and one for 9 pin sockets. They're used to clear a socket before inserting the tube. They usually come with a matching socket for straightening the pins on the tubes. Every radio shack and electronic space on ships has a set of these. I have mine mounted on the edge of the shelf over my bench.

Good going Leonard. Creativity is what makes radio fun! Your stuff is always interesting. Today was a great day here. I made my first contact with the 6sn7 rig today. Worked K2TPZ in Baltimore. Was ruff going as the big guns were all over us pounding away but we made enough to exchange signal reports and QTHs etc. Going to try again tomorrow. Annoying when a hi power stations sends QRL then CQ without a break. Now the only rig still begging a QSO is the rat trap 45 TNT. Been running the 211 Hartley a bit. That is fun even if I run it at somewhat moderate power. It works pretty good now. Nice feeling seeing that BIG monster tube sitting there. When I get over run like I did today by big power stations I am tempted to put the full 1250v to it and send "Go ahead son, Make my day!" Right now I run it about 1/3 throttle and should probably leave it there. Anyway as many of you well know first contact on a new rig is always a thrill. Also working on a crystal set project idea i got. Test worked fine but I want to try it later tonight before I say much. It is a shortwave Crystal set.

Group,

Yesterday I posted the below inquiry as to the use of Socket Wiring Plugs (see attached photos). I received two replies, one from Roger/K1TG and one from Leonard Meek (see Below). I would appreciate any other inputs from anyone who knows about these gizmos as I consider the question still open for the following reasons:

If they were intended for cleaning sockets, why aren't they called Socket Cleaning Plugs instead of Socket Wiring Plugs, and if simply a tool used once per socket, just as pin straighteners are used once per tube, why do you need a set of 10? The set of 10 suggests that up to 10 might be used simultaneously for some purpose. BTW, I have the matching 7-pin and 9-pin pin straighteners and they are manufactured by the same company; Star Expansion Products Company, New York, NY.

All of the miniature tube sockets I have, whether with phenolic, Teflon, polystyrene, or Bakelite bodies have their pin sockets sealed off at their bases before their solder tabs emerge under the socket body. Thus, inserting these plugs would only push any detritus further down into the pin sockets and trap it there. Also, solder wicking from the solder tabs to the pin sockets is not possible. The exception to the above is wafer sockets. These have their pin sockets open underneath, so they CAN be cleaned by inserting these plugs, and they are slightly susceptible to solder wicking, but only through sloppy soldering as the solder tabs are located about 1/16-inch away from the pin sockets.

Gentlmen, any other ideas? Mike, W6MAB

Subject: [AWA Group] Gizmos [2 Attachments]

Does anyone know how these Socket Wiring Plugs were used??? I can't think of any use for them and haven't found anything on the internet regarding these gizmos.

Mike, W6MAB

Hi Mike,

I am making a SWAG here but what about preventing solder from wicking up the socket contacts?

Roger/K1TG

There are two of them; one for 7 pin sockets and one for 9 pin sockets. They're used to clear a socket before inserting the tube. They usually come with a matching socket for straightening the pins on the tubes. Every radio shack and electronic space on ships has a set of these. I have mine mounted on the edge of the shelf over my bench.

Crystal set experiment was a success. Even in not the greatest conditions I could copy a station on 3215 at an understandable level. I could just hear CHU time signal and up on 40 M I could hear a station but not comprehend BUT remember this is a crystal set. With winter time propagation I think I would be fine. What I did was take the detector out of the crystal set tank and the headphones as well. I put a load resistor of equivalent value in its place. I wound a 100 turns of 28 copper around the top of the coil right next to the Rf coil (main tuning) using is as a sort of audio transformer secondary , placed the rectifier ,cap and phones in that coils circuit and voila, working shortwave crystal set. The station on 3215 is in Tennesee and is 100KW. I am going to putter away at his and see were it leads. Tennesee is a fairly good haul for me from hear. I may add another 50 turns in the audio coil tomorrow to see if it likes it. The Tennesee station faded in and out from strong (for a crystal set to almost not there. I checked it on my two shack communications receivers and it was not especially strong tonight even on them although certainly sufficient. I believe the transmitter is in Morrison TN this time of night. Probably 300 to 500 miles ATCF from me. Anyone on here live near there with a ham call? I can check the distance on QRZ then. I used my long wire to feed the crystal set and it was grounded. It has a few turn antenna winding. The crystal set I normally use on the shack for monitoring rigs I am testing to be sure they are where I think they are as crystal set are more honest then superhets. (no IF to confuse the issue and only hear what they are tuned to.)

Hey Don, what do you think you're getting on your crystal set, distance wise? I've dabbled a bit with crystal sets, but everything from here is DX.

Good going Leonard. Creativity is what makes radio fun! Your stuff is always interesting. Today was a great day here. I made my first contact with the 6sn7 rig today. Worked K2TPZ in Baltimore. Was ruff going as the big guns were all over us pounding away but we made enough to exchange signal reports and QTHs etc. Going to try again tomorrow. Annoying when a hi power stations sends QRL then CQ without a break. Now the only rig still begging a QSO is the rat trap 45 TNT. Been running the 211 Hartley a bit. That is fun even if I run it at somewhat moderate power. It works pretty good now. Nice feeling seeing that BIG monster tube sitting there. When I get over run like I did today by big power stations I am tempted to put the full 1250v to it and send "Go ahead son, Make my day!" Right now I run it about 1/3 throttle and should probably leave it there. Anyway as many of you well know first contact on a new rig is always a thrill. Also working on a crystal set project idea i got. Test worked fine but I want to try it later tonight before I say much. It is a shortwave Crystal set.

I don't know what the distance is Leonard. driving distance I know but As the crow flies I usually get from QRZ.com by popping in the Ham I talked to,s callsign. They give antenna to antenna distance. HoweverI don't offhand know any Tennesee call signs to install. Larry, Mike and Bill are all just under or over 300 miles from me. I imagine Tennesee is that an perhaps a bit farther so I will say under 500 and more then 300 till I know for sure. This all came about because of the loop thing. As you know because of our association on regens I have been talking about the Clough patent and absorbtion loop regen control. It was because I had developed that slugabsorb regen design that I knew immediately how the loop modulation worked when Lou showed us that picture. So I was working away in my shack on my latest rigs thinking about the recent discussion on absorption loops in regen control and I for some reason wondered if the principal could be used in another manner. I always liked Crystal sets and always have a few around including one ancient factory made one. I don't usually wonder long. So yesterday I was wondering and decided like usual stop wondering and find out. The whole mod took less then 15 minutes to do on my shortwave shack monitor crystal set. I could tell I had a signal even mid afternoon but conditions on 80m were weak so I set it all up so I could test it when I got home last night about 10 PM. First was would the signal transfer from the tuning coil to the audio coil as I am going to call it here forward. I had already checked it by monitoring my cyclops transmitter in the shack so I knew that at least worked. Would it be any better then a normal crystal set was the next question. When I could copy the station on 3215 at comfortable volume except for fading and when I checked with my DX150 (a very good early solid state rx) and my DX390 digital I found the reception of the same station on both no better then on the crystal set. Certainly louder but still fading from strong to oblivion. I was surprised to hear CHU. I use CHU to check if 80m is open all the time because if I can hear it here then I know my signal will get out or better said if I can't hear it here I know there is no point in transmitting a CQ. I have never heard it on a crystal set before. So this is just the initial test. How much load to out in the tank circuit and can the antenna coupling winding be improved are the next questions. Also does the set respond to more winding in the audio coil or does it want less. Where is the sweet spot? Etc etc. What happens if I make the coils much larger. Anything? Nothing or neg results.? I don't know at this point. I just know the basic concept worked. I hope to explore it further during the coming months.

Yesterday I posted the below inquiry as to the use of Socket Wiring Plugs (see attached photos). I received two replies, ... I would appreciate any other inputs from anyone who knows about these gizmos as I consider the question still open for the following reasons:

If the Plug pins are slightly larger in diameter then the tube pins: You wrap leads/component wires around the Plug pins. Aligning both, you slip the wiring down on to the tube pins and solder.

Guessing Lou

I'll make a guess. After the tube sockets were mounted in the chassis, these gizmos were inserted into the bottom of the sockets and served as wrapping posts for creating wiring harnesses. They simply held the wire ends firm temporarily with a wrap or two.

11758. New HB Xmtr Using a 2A5 - Update

Yahoo group: AWAGroup (2014 — 2016)
Date: 2015-09-06 21:13:29 UTC
From: Bill Stewart
Topic: 11758 Message: 11758

After several weeks of playing with the 2A5 rig at a B+ of about 375vdc, all seems to be operating ok. The p/s was a Heathkit bench supply so there was no worry about the tone. I was having so much fun using the 'lil rig that I was slow to get to the re-build or the HB p/s. This past week, I finally got to the p/s and threw one together using a PTOP xmfr and choke, junk-box parts and an 80 tube. I fired it up yesterday and it works great. Only problem was a bit too much B+ so I put in a dropping resistor in the ct lead to gnd and now have the recommended 500vdc under load. I had to add a couple other dropping resistors in the filaments due to higher line voltage than when the xfmr was designed, but so far no smoke or bad smells. I have made a few QSOs, the tone is T9X, and the p/s voltage drop is not bad. It appears that I'm getting about 20 watts input, which is almost twice the previous input. More tweaking and playing over the next few weeks, and then maybe I'll get to the rebuild and get this project finished.

Wow ! Nice going. I have been watching for you. So far I have missed you around 7036 or do you have a new spot you like. I check the RBN several times daily.
I have an 80 tube, in fact a couple and have been tempted to build a proper supply here. I am still trying with the 45 tnt (rat trap) to get a QSO.(80M around 3530 to 3550) So far nothing. It is putting out good power so I don't know why I have come up dry so far. Sounds like you are having a ball. 20 Watts is pretty decent. I was just re-reading the stuff you sent today and pawing through my tube stash to see if I had even a 47 (found a 42, Close but no cigar)
Your efforts though inspired me to get off my duff and back at it so I rebuilt my 211 Hartley and made a tripler supply and have had it on the air successfully. (40M) I had thought I had smoked the tube but not. It was a weird deal and not really related to the tube. I had to laugh when I found it. If I get a qso on the rat trap 45 TNT I can move on with my life and projects. Any pics of your PS?

Don, if you want to build a version of Bill's 2A5 rig you're in luck -
the 42 is the 6.3V heater equivalent of the 2A5 (and incidentally, the
6F6 is the octal equivalent of the 42).

Don, the prices aren't all that bad on eBay for the 2A5...maybe other places too.
Take a look on the web...you might find them at a good price.

Thanks Larry, I knew the 42 was a fairly strong tube as I have played with it as an audio amp but I didn't know how it compared before. Thanks for the info It came out of a old 1930s set. I think a 1931 or 32 Grimes and I have the socket and all. I would not feel guilty using it. Meanwhile I have been running my last regen. A 56 and 58 tube set. I thought it was working pretty well but last night just for fun tried a set of R14 Sig Corps phones (instead of my Brandes) on it. Wow! Nice radio! They pick up a lot less hum and I can hear the weaker signals in the clear. I also tried it on the untuned beverage as opposed to the long wire. it sure likes the untuned better. It has turned into a decent set. Meanwhile I have been testing the rat trap 45 TNT. It has gone un successful in ops. I know it is getting out so it must be the soft whoop throws potential contacts not used to old timey slightly imperfect radio. I bricked it today (not really, may have been a guest operator running the brick) and went for a drive with a portable. I could hear it several miles away clearly so I knew it was getting out. Then my brother was here. he has a SW navy receiver like Joe C has and so I had him listen just before lunch from a few miles away and he could copy it so I know it is getting out. This is the first time he could hear any of my 1 tubers , even the ones some of you have worked me on so it is doing the job. He is just about where my signal leaves the ground or perhaps first bounce. I'll just keep trying till I am successful in a contact(3536)
It actually has more stomp then my other 45 TNT. Bill, I could buy a 2A5 I guess but I think I would be happy with the 42 as it is also period correct. Too hot outside for this old bird today so I am playing in the shack till it cools a bit. (working on a 10m rig in a file box with PTO RX and TX)

Don and everyone,

The Classic Exchange is coming up, the CW portion will run on Sunday, 9/20 and Tuesday 9/22, and it's a great place to make contacts with a QRP rig. I had a power failure several years back and the only rig I could get on the air was a battery-powered Ten Tec Argonaut 505. I worked coast to coast from New Mexico on both 40 and 80 meters. I also regularly use a 1941 Meissner Signal Shifter with about 8 watts output on 80, 40 and 20. A number of times I have worked Wilson, W4BOH, in North Carolina on 80 with his Meissner Signal Shifter, two-way. The CW CX concentrates on frequencies around 14045, 7045 and 3545. If you can get a crystal around one of those spots for your 2A5 rig, I'm sure you will make multiple contacts. 20 meters is most active during the day. 40 warms up in the later afternoon and evening. 80 is most active later in the evening and into the night time hours. Make your 2A5 rig into a Tri-Tet and you'll be able to get some good RF on 20 meters out of it. The CX starts at 9 am EST and runs to 3 am the next morning - to give the guys on the west coast "equal time." You can get more information on the CX web page, http://www.classicexchange.org/ . Everyone is welcome.

Yes I am watching for that one. I am not good at contests but if Paul (BUG) is on he knows where I am before I go there. An Lou usually finds me too. Like to use all my one tubers for that one.
I started the 42 build today. Chassis work is done and chassis painted . Tube socket mounted. trying to decide on coil style and am wondering since it is a pentode of sorts perhaps I should do an ECO (ECO hartley)instead of being rock bound. I am building it to be a match or twin to the 56/58 regen. It will probably be a 40m only rig. I will have to think about this overnight. Finished the 10M file box radio station. Installed the modulator transformer and circuitry this afternoon and gave it a whirl. Need some 1/4 phone jacks from a decent source. The Radio Shack (now "The Source" here in Canada) are absolute crap. Nut thread doesn't match and so wont tighten. I have been wondering about a music shop as they sometimes sell Guitar parts for lectric guitars. They might have a better quality one. I am almost afraid to mail order because I know where they will come from. I am so tired of crappy made parts! My supply of originals is exhausted.

Tonight at 22:20 hrs I got a reply from Bill KB2RAW in Sidney NY. He took the time for a quick QSO and so all my rigs are now seasoned veterans. He has a very good fist and is really easy to copy. My signal report was pretty good except for the T part. (495)Maybe the whoop is what hurt me there. The rig cools a bit when receiving and takes about a half minute to warm back up and come back to the same tone. He asked how many tubes I had. Just one was my reply. Anyway I appreciate the kindness. It is probably not his thing but he heard me banging away there and took a few minutes to make my day. Decent fellow I'd say. I'll be Ok now. Still grinning!

Morning Don,
Have had several hour long QSOs and shorter ones, with the 2A5 TX and P/S
and no smoke so far. So, guess the time has come for the rebuild. But, just can't stop
using the 'lil rig as is. I think I have tweaked it about as good as I can. Still not real
sure just how much the output is but the input is around 20 watts...hopefully I'm getting
at least 10 out. I've attached a pix of the 'rats nest' p/s. Had to use several dropping
resistors to get the filament and B+ voltages correct. The xfmr on the left rear is for
2A5 fil. and p. lamp. Think its a Radio Shack 12.6ct jobby, but will have to work till
I can find a proper 2.5vac xfmr. Congrats on making the QSO with the 2-station...those
events will definitely put a smile on ye ole mug.

Ah Bill you're my hero!
Hour long QSOs on CW . I can not imagine. Longest I ever had was with a stranded weather researcher from Japan who was stormed in in Antartica. He said he had not had any contact with anyone on 30 days so I hung in till he got tired. Sent me a QSL card when he finally got home. That was back when CW was my normal mode. Wish I had kept it up! I used one of those gold RS transformers in my bench supply too. Here is how I solved the problem. I run 5 volt tubes, 6.3 volt tubes and 2.5 volt tubes so I installed in my bench supply a automotive heater switch from the early days. for some reason they still make them and sell them I buy them here at Canadian Tire but I am sure NAPA sell the same switch. They were for multi speed heater fan control and are very HD. Back in the 6 volt days. I put one in the heater supply in the PS but sometimes for stuff I don't always have on that supply I install one right in the radio. I feel no shame as it says HEATER right on it. It does a real nice job of giving me heater voltage options.Cost me here about 17 dollars can which considering the versatility is a bargin. In fact I can run. either a 5 volt or a 2.5volt when I choose I know right now some are getting wound because it is a car part however if anyone should thing this is just my dumb idea I am sure it was done many times before probably decades before I was born. Now my PSU can handle any common tube heater voltage. Like hook on phonics it worked for me.
Yes last night was a blast. He asked first how many tubes are U running? I said "just one" and then told him it was all built on a real rat trap. He emailed me later and said he thought I was joking but I sent him a photo when I sent him my Email QSL card/pic. It is actually a fairly powerful lil rig. Other then my 211 Hartley probably next on line. I have the 42 rig going as of an hour ago. I built it as a VFO ECO Hartley pattern. I have a pi tuner here I built so I will just pump it in there since I would anyway rather then build a output plate side on the chassis. At least for now. It seems fairly stable and not bothered by my hands. I finished making the front panel and the glue is drying as we speak. You are getting real good power I think. my inital tests with the 42 are only about 6 watts input at 316 volts. I don't know what it will be like under full load and I had no parts values so I used what I normally use on initial construction. I will do voltage tests under load and adjust screen and grid voltages later. Loading it down might make it grunt a bit too. I love your PSU lash up. Brings back very recent memories. You certainly got value for your efforts with this 2A5 rig! Still hoping to work U.

Date: 2015-09-09 19:18:51 UTC
From: JAMES HANLON
Topic: 11768 Message: 11768

Don,

Have a look at what Antique Electronic Supply (www.tubesandmore.com) has in the way of 1/4" phone jacks. From their Home Page, scroll down to "Jacks and Plugs" in the menu on the left. With just a quick look I say part number W-SC-11, a 1/4" Switchcraft type 11, 2 circuit, open circuit jack for $1.80, W-SC-12A, a Switchcraft type 12A, 2 circuit, normally closed jack for $1.95, and several others.

Also about the CX, it's more of a QSO Party than a "contest." There are a lot of friendly folks on who will be glad to chat for a few minutes about your and their gear.

73,

Jim, W8KGI

11769. Eddystone 2015 report

Yahoo group: AWAGroup (2014 — 2016)

From: dan.w7oil@...
Topic: 11769 Message: 11769

The Eddystone 2015 has been fully wired, the first coil wound and ready for smoke test. Turned it on and . . . no smoke. No function either. I found the 90 volt battery had sagged to 80 volts and I was running 1.5 volts on the filaments. I'd really like to put 2-volts on the filaments. This was enough to see if the voltages were going where they were supposed to. It all appears OK there. I've had enough for one night. It's off to the dollar store tomorrow for more 9-volt batteries to replenish the 90-volt battery. There's a chance the reaction winding is backwards too. A couple photos of the almost finished unit have been posted in the photos section.

More later,
Dan - W7OIL

11770. ECO 42 Transmitter

First of, thanks for the 1/4jack info James. I need some other stuff anyway so will include it in my order.
Now today I have been to Electron Coupled Oscillator school. I just finished it and had it calling CQ a few minutes ago. I am only getting about 3 watts out but they are good watts.Stable and solid. I like the sound.
I reserve the right to further experiment with the grid leak resistor and screen voltage is bit high. I can sort that ouver the next few days, It has been a learning experience. i had no circuit just a general description and token schematic. I put it on 40M . Time for bed.

From: dulmagedon@...
Topic: 11770 Message: 11771
Attachments: 3 described; binary payloads are missing from this source WARC

It is all done now . Screen voltage in line and gridleak optimized. Works into he Pi tuner nicely but also usable without. I wired the receiver with a power plug for my PS (any of them as they all use the same wiring pattern) and wired the transmitter to the receiver so they sit side by side on the shelf with a bit of room, The key (split B-) comes down the middle to the key below. The regen is on the beverage for listening and the Tx is feeding the tuner which is feeding the longwire. I tried it out just now a a unit. I think it is a go. ECO was a good excercise. I had built one a few years back with a mixer tube but this is the first I did one like this. I guessed at values to get it going then measured voltages and adjusted accordingly. Was workable though even at the guess stage. It could use a bit stoughter PSU but this one is quiet and handy so for now it will stay as is.

Subject: [AWA Group] Information needed

Gentlemen,

I am looking for any information on a Bliley Vari-X oscillator. Bliley published a circular (D-2) but

I have not been able to find it online. I did find an article in the June, 1940 issue of RADIO with a

circuit diagram and brief notes on its operation.

My plan is to build one. I'm could use a clean picture of the front panel and internal layout or

pictorial. A scanned copy of the Bliley circular would be a great thing to have.

As always, I appreciate any help I can get. This is a rare bird indeed the high coast and WW2

cut any hope commercial success.

Thank You.

So far no contact with the 42 transmitter. Tried a sked with a Ham north of me . We can work on 80M as he worked my breadboard station twice but 40m is a different game . We can't hear each other so we are probably in the wrong spot for typical 40m propagation. I am running low power but he isn't so I feel that is a safe assumption. We both could copy the same other stations who were sharing the spot from time to time. So today after trying again I reached over to Big Bertha , my 211 Hartley. I plugged in the key and antenna and hit the power switch on its tripler PSU. A couple of minutes to warm up and I hit the key. Fun to run. Shack FS meter can be heard hitting full scale on every key stoke. The tone in the monitor sounds different. The monster tube sheds quite a bit of light from its almost white filaments. Has a strongness about it little rigs don't. I enjoy running it now and then.
I am toying with the idea of building a 807 PA for the 42 ECO rig. I will give it another week and see how I make out. I am never happy till I have at least one decent QSO on a new rig. BTW The new regen that goes with the 42 rig is turning out to be an enjoyable set to run. It works very well.

Don,

Since you are thinking about adding an 807 amplifier to your 42 ECO, you might be interested in having a look at the schematic for a Meissner Signal Shifter, especially the EX model. The 42 is the equivalent of the 6F6 which the EX uses for its oscillator and doubler, and the EX also uses an 807 as its doubler/power output tube.

Thanks Jim. I will have a peek. I thought about bidding on a Meissner a few weeks back. My no 19 uses a 807 final although not pushed very hard. In fact one wonders why they even bothered to use a 807. A 6v6 would have done the same job. Anyway I have a spare 807 and a socket so it wouldn't take much to do. Also have a dozen NOS 1625s for my Arc 5s but no sockets and a 12 volt heater complicates a simple build. I will try a few more days on 40m before I capitulate. It should be OK as I have done more with less. I will check out theX model Schematic. BTW in my 43 ARRL book after I have this built and running I found a 6f6 vfo cicuit built as a ECO. Almost identical to what I did except for one section. I hadn't seen it before.

Well...It LIIIVES!

I got this cranky "illegitimate child" to work tonight after a long hard battle and a few modifications - like most of the circuit! Seems the Yankee tubes do not take too well to the English circuit. I finally stripped it back to parade rest and started with a "tried and true" (?) circuit from the 1937 ARRL handbook. If it's in the Handbook it's gotta work, right? 8^0 I did without the RF amp as the Eddystone didn't have one. The bugger at least looks like an Eddystone AW2 and with the tuning circuit intact it should act like one. My brain is fried more than a basket of french fries tonight so fine adjustments will wait for morning. So will photos.

Glad you got it working and I am glad you nixed the RF amp. the LAST thing a regen needs is improved senstivity. It is akin to putting stilts no a giant..(already too tall) A good regen can hear the hum in the wiring in you house walls even when on a battery. the Absolute no 1 trouble with many regen builds is too much antenna and too much front end gain. Also tuned antennas. A tuned antenna creates flat spots because a regen is simply an oscillator that can not quite oscillate (not quite enough feedback bit almost.) with a set of phones somewhere in the B circuit to sense changes in load. Armstrong sircuit is the most common but is also the most sensitive (tickler coil style) A hartley is the easier one to build and some work very well. Antenna coupling is another trouble spot. A gimmick cap is often enough or a ceramic trimmer but on of very low value. When trouble shooting a good trick is to take a screw driver and touch it to the antenna connection. If you hear a click it is ok and if you don't it is too tight so open the antenna trimmer or untwist the gimmick cap till you do Usually you can find a spot that will cover the band or most of it. Also they work better with a fairly narrow bandspread, say for instance the 40 ham band 7 to 7.3 more or less. then they can be easily run without constant retuning.of antenna and regen control. Folks with good intentions often add Rf amp and all kinds of goolglyjunk thinking well it only has 1 or 2 tubes so it needs all the help it can get when in fact the signal goes through the tube several times growing each time and sensitivity especially is remarkable even compared to the most expensive Rx you can buy even today. Just for instance there is nothing my TS830s can hear that I can not hear on my 6sl7 regen. Downstairs in studio B I was recently comparing the DX390 recently to the 56/58 regen I built a couple of weeks ago (A hartley) Whatever is on the DX390 is also available on the Regen. Where regens are limited is selectivity however with a regen the beat note is easily controlled so you put the Cw note where you like it and you can follow it easily even in QRM because no two will be exactly the same tone. It works better then you might think. Also some regens lack volume. That would be my complaint with the 56/58 set. It would not be hurt by additional audio stage. The 43 ARRL circuit would drive a speaker till I installed a resistor in the B+ to kill some power. I am sorry if this is too much info. I offer it because this is sort of regen central with 7 currently in operation and in the hope it may be of some use to you as you push through to the final polish on your beautiful project. Not every published circuit is wonderful. Over complication is the regens enemy. I agree with your ARRL assumption though. I have found it so. Have a good rest and all the best as you push to the end. That set has a real nice appearance. Not a skill I have here.

Don,

The earlier, plug-in-coil Signal Shifters all used a 6L6 for the output amplifier. The last of the line EX version used a turret for band switching and an 807. The manual for that version is on the BAMA site under NewSS.

I'm in the process of de-acquiring a lot of my boatanchor collection. I just turned 77 in August, and it's time for me to get real and place this stuff with folks who will appreciate it rather than leaving it as a problem for my wife and kids. I do have an EX that I'm not using that I need to pass on eventually. (We just had a neighbor die and he left his wife with five horses and a camel!) If you might be interested, let me know. I'll try it out to see how it is working and take some pictures. I also have the FMX FM modulator for it.

Well even at the young age of 65 I resisted bidding on the last one and for exactly the same reason! I figure the XYL will have enough fun trying to sell the dragster when i'm gone never mind more radios! I have been watching the performance of this ECO rig, It has I believe enough stomp to do the job as is. I remember banging away on my Bare Essentials rig off and on for a year or so with no luck then someone here suggested a sked and I discovered it worked just fine. Same with my TNT the 45 tuber. Banged away fr a year on CW. One day I got a nasty note from an aggravated ham telling me he heard me sending cq but it had a strange sound. I was thrilled it was getting out as he was a fair distance away. Nowiknow that for most the sound of a keyed power osc is too much for them and they think they might go tojail or something if they answer the "strange" station.In the BK I discovered they all work and just fine too. Inthink some are just nervus about working a vintage sound station and that is understandable. This has as much output as two of my other ones so I am just going to keep banging away while the XYL watches Jeapordy (I can't stand the show!) Sooner or later I will get lucky. Tomorrow VE3CDX is coming to see some of my vintage style gear. He worked me almost right away when I first fired up the breadboard rig and found me again on it a few days later. He lives about 60 miles north of my but is in town tomorrow morning and asked if he could stop by. I think I will set Big Bertha up for him to operate on 7036kcs. He is a good Cw operator. Might be fun for him to run a big 211 Hartley. He belongs to AWA and such and has a strong interest in these type of rigs. Mean while as far as the 42 ECO
rig goes I have the 807 set aside and its socket just in case. Think of it as a threat to the rig to encourage it to do its best.

Don

A properly designed regenerative receiver with an RF stage can work very well - witness the National SW-3. The RF stage isolates the detector from the antenna, eliminates pulling effects due to the antenna swaying in the wind, allows adjustment of signal level with the gain control, and cuts way down on radiation from the detector. You have to be very careful to decouple the RF stage from the detector with appropriate shielding. National published a good development article on the design of the SW-3 in QST which they bundled with the SW-3 manual. I can copy it for you if you are interested.

Yes so I have been told however, here in the trenches having built some both ways I think an Rf stage on a regen is like a Nun in fishnet stockings. Nice to look at but probably not a real good idea. I have no antenna sway changing freq issues, more then sufficient sensitvity and I can hear the rf stage equipped ones regen on a nearby receiver just as well as a not rf equipped one. Both 25 to 30 feet away are undetectable. If there is one thing I have learned in life in both my hobbies MORE is not always better. Often more gives back less. Simple basic done well will 90% beat complicated exotic hands down. I intend when I get time to explore an antenna tuner (unturned or passive rf stage) just to see how it affects the regens. It should only take a few minutes but I haven't had a few this week yet. don VE3LYX

Also witness the RAL and RAK - which both have a regenerative detecter
and 2, count them, 2, TRF stages. Their purpose is not so much to
increase sensitivity, but for antenna isolation, as Jim says, and also
to improve selectivity. It's not just a matter of being able to use the
filter between your ears - a strong signal nearby can pull the detector,
and even "block" it, so that the weaker signal you're trying to copy is
lost. The TRF stages help here to give greater rejection of strong
signals close to your frequency.

73,
-Larry/NE1S
...who owns and uses an RAL, RAK, and SW-3, as well as simple homebrew
regens.

My breadboard rig has been a lot of fun. I have worked a few including Lou. One I have worked more then once is Jim VE3DCX. Jim is a AWA member and is Net Liason also with the NJTN . He does a lot of CW work
and always has his ear bent for a Vintage rig note. He was in Belleville today and asked if he could stop over and see the breadboard station he had worked. He has a strong interest in building a BK suitable rig. He has a good supply of tubes. He came today and I gave him the fifty cent tour. He took some photos of the breadboard station and I showed him the rest of the rigs downstairs. I had set the 211 Hartley Big Bertha up on 7036kcs and let him have a go with it. He is very comfortable on CW. In fact I suspect he prefers it. He handled the big rig well and it was fun to watch. I saw him glance at the FS meter noticing it was banging full scale on every key stroke. He was surprised that from cold start up to full heat it varied very little (maybe a 1/4 kc if that) and commented on it. He had an appointment in a town north of Belleville that kept our visit limited but warned me, "I'll be back!" Always nice to put a face to a fist. Also interest in vintage rigs and Cw as well as tubes is not huge in my area. Jim lives 60 miles north of me ATCF and says it is similar there. Glad to know there is at least one friendly face nearby. I predict he will be on air with his own TNT or Hartley for the next BK. He told me he was on the net but not using his narrow filter and could hear this vintage sounding note just barely to the side. He tuned over in time to hear the call and decided to reply. I am gald he did.

don Ve3LYX
Some of you may know him from vintage QRP group or the New Jersey CW net.

11787. Power Supply from 12 volt solar source

Yahoo group: AWAGroup (2014 — 2016)
Date: 2015-09-24 16:14:01 UTC
From: dulmagedon@...

Attachments: 1 described; binary payloads are missing from this source WARC

I have a moderate sized 12 volt solar cell on the house charging a single 12v deep cycle marine battery. I use it for a 12 volt source and run my vibrator power supplies for it for my No 19 set. I use the vibrator supplies for other sets too as it is my own concoction rather then the original Canadian set vib supply. I piggybacked two to get into the 550 volt range for the No 19 final and pull the 275 for everything else of the first supply. It worked pretty good but I built a Ac supply for the 19 but still used the vib supply around the shack quite a bit. I decided to update it the other day as 120W plugin inverters were on sale. I bought one and tried to see if it would run my complete breadboard stations PSU and it did without even a whimper. key down and all so i knew it had the suds. I made then a voltage doubler rectifier unit. I used the same circuit I used on my 8111A linear supply as it is the quietest double I have seen so far. I put a bleeder resistor on it to give it some load and tested it. 318 volt Dc. Seemed good so i bought a three in one adapter and bought another 120W inverter. As luck would have it I couldn't find another identical but after two days of looking just bough another 120w and will match them perfectly later.I paid $30 each for them. I built an identical rectifier doubler. I wired the three in one adapter for better current handling and installed a 2 prong trailer plug which is what is used in my vintage shack for all 12 volt access. I tested the new inverter just to be sure it could also handle everything and had no problems. I lashed it all up on a board and tested both doublers . Each produced identical voltage and both were working into a bleeder resistor for load. Then I piggybacked the two doublers. Pos to neg and fired it up again. now working into the bleeder resistors from left hand pos to right hand neg 624 volts DC. I installed a cigar lighter plug in to the centre open hole in the three in one adapter. I now have 12volt Dc access there up stream from the inverters so independant. I could use the 12 volt supply to charge two six volt gel cells and that would give me from left to right 318volts DC 6.3 volts DC , 12.6 volts DC and 624 volts DC. I tried to use the inverters as is so they can be serviced or borrowed without ruining the supply. I will replace the oddball with a matching one as my squarehead does not like mismatches. (alles in ordnung). I am hoping this will be a usable supply for my vintage low power rigs . Testing begins later this week. Winter propagation is returning. 40m is hopping most evenings.

11789. de K1TG - Part(s) needed

Yahoo group: AWAGroup (2014 — 2016)
Date: 2015-09-30 14:56:42 UTC
From: Roger Kuchera
Topic: 11789 Message: 11789

Gentlemen, Another project another odd part needed. If vintage restoration and/or projects were easy, everyonewould be doing it.

I need either of the following:

1. A defunct Weston 506 meter case with an unbroken glass.
2. A working 500 Volt, Model 506 meter (or equivalent physical size).

The type 506 needed is the round, 2.25" case (panel hole size). I can trade or buy in any case. I havea fair number of Weston 301 milliamperes meters. I have a few oddball/vintage (non-WW2) cases also.If you want to swap, let me know your preference as to range and make.

As always, any help is appreciated. Thank You.

Roger/K1TG

11790. Does anyone have the April, '78 issue of QST...

GM,

Does anyone have the April, '78 issue of QST in any form? In the RX article is mentioned the upcoming month of the companion TX issue. I need that info.

Tks, Lou

So, what do you need? The April issue or the May issue. Or, do you just want to know what it says in the April issue about the upcoming article, which is how I interpret what you are asking for, but that alone does not make much sense to me. 73 - mike

Hi Lou,

Although there was no mention of the transmitter within the RX article,
I began scanning the indices of subsequent issues and found the
following article by the same author (W1VD, a friend of mine, BTW):

/A 20-meter, VXO-controlled, 6-watt transmitter/, Jay Rusgrove, W1VD,
QST December 1978, pp11-13.

Hope this helps.

73,
-Larry/NE1S

That circuit is also in the 85 handbook and if memory serves me the 82 and 83 although I no longer have them.Back then I etched a board and bought a lot of the parts but ran into a problem finding the proper toriods.
I have seen the board in the last year or so in one of my junk drawers and still have the MRF472s. I found another circuit at the time that used radio shack Rf chokes in the filters instead and built it. It had a single transistor output but power was close. I still have it, in fact it is right beside me and is on 80M. When I designed and built the Slugabsorb regen rx I put it in the same case and use them as a pair,
Fun stuff

11809. Wayback radio SW Crystal set

Yahoo group: AWAGroup (2014 — 2016)
Date: 2015-10-02 10:54:41 UTC
From: dulmagedon@...
Topic: 11809 Message: 11809

I have always had an interest in crystal sets and have a few. One I built for use in my shack when I started playing with TNTs and Hartleys etc. The reason being that superhets are prone to image problems and will even hear at IF freq sometimes so I needed something that i could count on. I use it quite a bit all considered because doesn't lie to me. last year when Radio China was dominating 40M in the evening I clipped it to my long wire to see if I could hear China. I could just tell it was there and catch a word or two which of its self was a surprise. A couple of weeks ago I got an idea to add a third coil and move the detector and phones outside of the rf section. Much to my surprise it worked. Still needs some rubbing but I can sit here on a decent night and listen to Tennessee and NC and once Florida at comfortable levels (no further amplification needed or desired) in my earphones on 49M. Perfect ? No as the tuning range or sweet spot is quite limited but very interesting to be hearing shortwave stations that strong with no amplification. So I went further. Thinking it might be some kind of a fluke with my antenna and ground in my vintage downstairs shack (studio B) I brought it up stairs and tried it on my 80M 40M inverted vee and my upstairs beverage. Same results although the longwire is the best for it for sure. Was it something that could be duplicated? I wondered so I built another, winding the tuning coil on a 3 inch section of ABS 3 inch plastic pipe and clipping a spare 365 pf variable to it. I installed the diode and phones on the third winding (about 40 to 50 turns of #24) Sure nuf it worked. It isn't at the top of my to do thing however I will be playing with it as time and interest permits. Always something going on. Radio is a fun hobby!

Was out to an antique store today. The guy running must be in his late 80s or more and was talking about throwing in the towel in Dec as it is too much for him now. Said he was giving deals. I found a Speed X telegraph key. Black base and skirted knob mounted on a board and two pair of Allied Radio Lincoln Earphones. I know the earphones are probably just cheapies from the fifties however they had their connectors on them and both work well. the key I think is what is known as a EF Johnson Speed X. Black base, chrome (that means shiny . Might be nickel or whatever) lever and appears to be well made. As the stuff gets harder to find I don't pass it up if the price is good. I made him a offer way below what they were asking and after a minute he said Ok we can do it. Someday I hope to find a key with a shorting bar as I often need that however so far other then my Bug which I can no longer run (too stiff and unco-ordinated) I haven't run acrosss one at a decent price.
don VE3LYX
BTW he had a box of panel meters and the sign said $5 each. Two were miliamp null meters. I was tempted to offer him $50 for them all but had already spent my allowance for this month ;>)

Thanks Lou. It gets better.
When I first saw this I noticed the key was wired with lamp cord. I have and still always use lamp cord for my keys. Usually loop and tin the ends rather then buying eyelets. I noticed this had that also this morning and thought that's odd but never thought any farther. Tonite I went to hook it up and noticed the thumb screw nuts didnt work right. All of the sudden it all came back. I had a similar key when I was first licensed and the thumb screw nuts were not quite the right thread but would work if you didnt force them although they smetimes unscrewed underneath like this one had just done. I looked at the wood and realized it was a piece left from the nick nack shelf I built my XYL back then.(red BC Cedar) I got my other key which I have had since I was licensed . The lamp cord is an exact match and the ends are done similar. This is my old key I used on the Viking II. As unlikely as it seems as soon as I had trouble with the screws I knew it. I knew what was wrong and all the frustration of that old trouble resurfaced. Tonite after supper I went to the shop and chased the threads with a proper tap. (Didnt have one back then)Plugged it into the BE one tuber and called CQ. Home where it belongs.
I guess it is not that incredible as it was only 12 miles away where I bought it today. Still seems a bit over the top to this old boy. I wonder if he has the Viking and the CR5A rx. I am at least going to ask.

Roger,

RE: Meter, new plastic facing.

If you have any kind of antistatic material suitable for plastic I suggest treating the inside surface of the Lexan. The outside can be done at any time but that is not as effective as the inside. I have several vintage VTVM's and a Triplett tube tester that go nuts with static attraction at times.

GL with the project.

Another alternative that would work well is someone who does stained glass and there are many hobbyists who do as well as pros. The first part of their training consists of learning to cut weird shapes in glass. The XYL did this for a bit and made beautiful lamp shades. They are taught how to scribe it and have little nippers to remove the unwanted edges. I would think making a meter glass for them would be a piece of cake. And I used to teach my students in college "There is little in this world that can't be had for a cup of hot coffee and a box of donuts"

11821. Rubbing on my 42 tube ECO TX

Yahoo group: AWAGroup (2014 — 2016)
Date: 2015-10-13 01:52:33 UTC
From: dulmagedon@...
Topic: 11821 Message: 11821

AS you know I have had this rig running for quite awhile. So far no contacts. Not good. However about two weeks ago I became suspicious that the 42 tube was iffy. I had done about everything I could think of and it wasn't responding as one would expect. I checked with my supplier The Tube Store in Hamilton and they stock 42 tubes.I ordered one and right away warm up was reduced and power rose. I measured the heater resistance and there is quite a difference between the new tube and the old one so something was amuck. Still I wasn't pleased. I worked on it today and was at the point of taking it apart and redesigning it probably with a triode of some description. My eyesight is crap compared to what it used to be even when I wear glasses. Up close in the bright light I see one of my bypasses was not connected , just close. I fixed that and things stepped up a notch. I did a rework of the gridleak and all but eliminated the chirp. I did some work on the Power Supply too. Things moved forward a notch or two and I think it is now working much better. Power is equal to several of my more successful rigs if you can believe the shack meters and the note is dramatically improved. I called CQ for a half hour tonite around 7040kcs. I know it is getting out so it is just a matter of time. Come to think of it I haven't had a CW contact since this month began. Over in the corner just so I wouldn't forget how I whipped up a micronaut SS transmitter as well. QRPp.

I am good now. Had a good QSO with Garry WA1GWH today at 3 pm. He was using his QRP rig and I my 42 tube job. There was a bit of fading but when it was good it was fine. We wanted to know if we could hear each other on QRP style power and he wanted to do it on 40M so since I was tuned up on 7030kc we gave it a shot. Connected immediately. Made my day, he did.

Comment from user: I am a licensed Amateur Radio operator and am interested in learning more about the construction and operation of the early tube-based radios.

That's a good start, attic-ant. Yes, what is your call please? Welcome and 73, Lou VE3AWA

Hello, this is attic_ant. I picked that years ago because I live in a townhouse, and all my antennas are attic antennas. I've been licensed for about 14 years now, and have focused on qrp while experimenting with modeling, then building, various antennas that will fit in my rather small attic space, limited to about 20 x 27 feet. But with that, I can work 80-10M. I have various single band QRP radios built from kits, then upgraded to an Elecraft K2 kit. I've stayed with QRP because I enjoyed building my own radios, and 5 watts keeps my transmission from causing interference with my neighbor's TVs, etc, since my antenna is only several feet from my neighbors on each side.

I'm temporarily off the air as I lost my spare bedroom/shack to a new member of the family. But I'll figure something out. Meanwhile I've been interested in the early radio designs, but my radio circuitry knowledge and experience is limited to soldering together various QRP kits. I have never built radios from scratch, although I have the CD's for the old QST magazines, and have several old manuals from the 30's, so I have been studying the diagrams as well as looking at various websites that talk about early transmitters and regen receivers. I started picking up some general parts from ebay like transmitting capacitors and old dials but don't have a firm plan or design yet. My goal is to build a simple transmitter, a regen receiver, and a monitor, to have a complete single band setup, probably for 80 or 40M, assuming it is easier to get a stable transmitter for those lower bands.

Thanks for the invite, and I'm looking forward to reading through the archives and getting a better sense of how to get started on this.

Welcome Vic – Congratulations on the new addition to the family. Welcome to our group. There are some real experts on here that are super craftsmen and build beautiful transmitters and receivers of ‘20s and ‘30s vintage.

I looked you up on QRZ and notice you live in Sterling, VA. I lived in Manassas from ’76 through ’92, then moved up here. I was first licensed in ’63 and will be 70 tomorrow. Looking forward to hearing more from you on here. 73 – Mike

Thrilled with the contact I thought that would keep me calm but I have pressed on trying to make it better. i have tried a lot of things over the past couple of days and am back almost where I started but with improvements and a bit more power. I still want to try a couple of more things before settling on its final configuration. It now has a cleaner note than it did before which is good. It has a whoop but if you take time tuning it to peak the tuner then centre the freq with the transmitter tuning and recheck it is quite decent I think. Probably should have used less L and more C in the design and I can still do that. I even tried keying the screen which worked nicely except the osc would run lightly anyway (even when I parked the cathode with a resistor and bypass cap) which I didn't like so I changed it back to cathode keying. It is quite useable even now however I would like it to be just a bit better.
And while I am at it. Happy Birthday to the Birthday Boy. And I would like to thank you "Old Duffers" for letting a young lad like me play with you all. I feel like a child among men having only received my third Old Age Security cheque. Truth is we are most fortunate to have such an interesting hobby to occupy our time and minds rather then drooling on our bibs waiting to slip away like so many who did not foster interests other then work.Sad existence for some I think.

Folks,

I am in need of two, small 5-pin coil forms. Old tube bases would be just fine. Can anyone help me out?

thanks,

Jim Hanlon, w8KGI

I was working on the 42 tube this morning and even had it calling CQ but no cigar. I see prop report for today is poor to fair. So I reached over and switched on The Monster and called CQ. Instant answer from "The Falls".
Sure is a fun rig to run. I think it helps warm the shack too. Some days are just not QRP days. Today was one of those days here. Fun watching the in shack monitor needles pin on each key stroke. I only run it about 1/3 throttle but it seems to be enough.

Roger, Dave and Louis,

Thanks very much for your response! I should tell you what I'm working on.

After turning 77 last August and having a good friend/neighbor pass away and leave his wife with five horses and a camel, I decided that it was time for me to start finding good homes for most of my boatanchor collection. So far I've been working on the things up in the attic. One of them is a Millen 90800 transmitter in its original box. The transmitter itself came with coils for 10 meters, including a 40 meter cathode coil for the tri-tet oscillator. Since I have another 90800 in my on-the-air shack, I'd been gathering coils for the 90800 when I could find them. At this point I have additional, original Millen coils in Millen boxes for 160, 40, 20 and 15 meters. To make the set complete I just ordered B&W coil stock from Surplus Sales and some banana plugs from Mouser that will allow me to make a couple of 80 meter coils. I also need to make two cathode coils, one for 160 meter crystals and one for 80 meter crystals.

There's plenty of room on the 90800 chassis, so I could fit in quite a few different diameter and length coil forms as necessary. The original Millen coil form that was used on my existing 40 meter cathode coil is one inch in diameter and just short of one and five-eights inch tall. A couple of those would be my first choice. But something like the tube base from a defunct 807 or any five-pin receiving tube would also work just fine.

I'd be very happy to pay a reasonable price for a couple of forms and also to cover the shipping.

Let's all keep in touch so I don't wind up with an over supply. At this point I'm trying to lower the inventory, HI!

73,

Jim Hanlon, W8KGI

Hi Jim,
Will these work? They are 1 1/4 inches in diameter and 2 inches tall.
You would have to remove whatever is inside, but that should not be too hard. I have no idea where they came from, or what they were intended to fit.

I do not have any 1 inch forms.
If these will do, I can have them in the mail tomorrow, no charge. Please let me know.
Dave

Has anyone looked at Playthings of Past? I bought a couple dozen plug in coil forms from him a while back, 4 pin and 6 pin. I also got a couple of variocouplers from him, and he even threw in some green DSC wire to rewind them with.

Leonard

11844. Old QST and OTB mags

Yahoo group: AWAGroup (2014 — 2016)
Date: 2015-10-25 01:33:30 UTC
From: dulmagedon@...
Topic: 11844 Message: 11844

I came home a few days ago to find a large box of old 1920s and 1930s QST mags ans perhaps 50 or so OTB journals. I know where they came from. Jim VE3CDX. We had made a deal for he would trade these for one of my books. Seemed like I was getting the best of the deal by an ridiculous amount but he's was happy and so was I. Unfortunately I didn't know he was coming so I wasn't home. I will have to mail him his book. I just finished giving them all the once over, sorting them into must read and later piles. Of particular interest to me is the OTB Journals and in particular the Breadboarding articles. I even found a transmitter using the 42 tubes. I have been working on the 42 tube transmitter quite a bit. I have the power up if shack meters mean anything and the note is better and the chirp is almost gone. Drift is very minimal. Also i have been monitoring my hydro Ac voltage as occasionally I have had strange incidents. In the last 24 hours I have been as low as 114.7 volts and as high as 122.1 volts. All readings same meter same outlet. I have no idea what is normal but that seems goofy to me. It stays steady for awhile then begins its march downward and around. I am at the end (last house) on a rural system and my transformer Is an old green one. Last one left that I know of. It has been repaired several times over the last 36 years and once was even on fire. Apparently a ground lead got corroded and melted. My friend at Hydro told me because it is an old green one containing PCBs they will do everything they can to keep from changing it as disposal is a big headache now. Perhaps that is the source of my trouble but maybe not.I don't know. It is noisy (rf wise). I could tell the voltage was moving around by listening to my Tx in the monitor. Anyway. currently playing in and around 7030 kcs with the 42 ECO tx. I have been using with its matching regen as it works very well for 40M. Kinda fun doing it that way.
don VE3LYX
BTW I saw two of you mention in the OTB journals

I have been spending too much time trying to get the 42 ECO rig to run like I want. I am almost there but couldn't raise anyone with it today. As I have done several times before I reached over and switched on the 211A Hartley. I think I'm in love. It rarely fails to raise a reply on the first or second call. Was pounding brass Into Folsom PA today. Life is good.
don Ve3LYX
PS
The pic with Bruce Kelly above. Is that a spark TX or something with tube(s). I can't tell from the pic but love the flat metal spiral wound coil.

11851. RE: [AWA Group] Old Reliable

Yahoo group: AWAGroup (2014 — 2016)
Date: 2015-10-29 01:15:42 UTC
From: Edward Gable
Topic: 11846 Message: 11851

The picture is indeed that of Bruce Kelley, W2ICE. The transmitter is a 1 kW synchronous rotary gap that was built in 1914, by George Batterson, 8TC, later W2GB. Bruce and George were co-founders (along with Link Cundall, W2LC) of the AWA. Bruce was the first Curator of the AWA Museum. BTW, someone erroneously added the caption W2ICE/W2AN to the photo. Bruce was never W2AN. The transmitter is still in use today at the AWA Museum and is a real crowd pleaser. Unlike yesteryear, today, before we light it off the museum docents are required to ask the visitors if anyone has a heart pacemaker ! If so, they are asked to leave the immediate area – hihi. Also, most modern auto-exposure, auto-focus cameras stop working at key down. All recover thank heavens. Cheers,

Ed Gable K2MP/W2AN
Curator Emeritus
AWA Museum

I have been spending too much time trying to get the 42 ECO rig to run like I want. I am almost there but couldn't raise anyone with it today. As I have done several times before I reached over and switched on the 211A Hartley. I think I'm in love. It rarely fails to raise a reply on the first or second call. Was pounding brass Into Folsom PA today. Life is good.
don Ve3LYX
PS
The pic with Bruce Kelly above. Is that a spark TX or something with tube(s). I can't tell from the pic but love the flat metal spiral wound coil.

The kW spark transmitter is built into a tight wood box with no top. In the box is a frame that holds the transformer (115 VAC primary) and the high voltage capacitor made from layers of glass plates and thin metal. The box is filled with oil that completely covers the capacitor and transformer. The frame continues out of the oil and forms a shelf that holds the motor, gaps, oscillation transformer and other bits. Thanks for the interest. 73, /Ed k2mp/w2an

Several years ago I stopped by the AWA Museum in Bloomfield and got a tour from Bruce. It was a lot of fun and really informative to be toured around by him. I had my camcorder running as he talked about and demoed the spark gear. I posted the video to youtube at https://www.youtube.com/watch?v=ZHdR_7wdLWg

Thank you, Niel.

Although the new museum is truly impressive, what you show in your video is as I wish to remember the AWA Museum.

As to the call, W2AN. Bruce would use both it and his call during the various AWA contests of that period. For that reason I believe the connection holds.

One area I would like to improve on is my power supplies. Other then the one I built for my twin 811A linear the rest seem to be humdingers. I don't really know why. Two are very close copies of the "economy" power supply carried in ARRL handbooks for years . I have added filters bypassed etc etc but still not as quiet as I think they should be. So I would like to know what the rest of you use if you don't mind sharing.

Hi Larry:
I do have photos on the AWA site but I will put the latest and greatest here for you. The SS contest sounded like sheer pandemonium on the set but with neurlogical (neurotic? HI) filtering it was pretty easy to pick out signals. All in all the Eddystone-2015 is a hoot to use. Tube complement is a #32 detector and a VT-67 (a "militarized" #30)

11866. Upcoming Bruce Kelly 1929 QSO Party Announcement

Yahoo group: AWAGroup (2014 — 2016)
Date: 2015-11-11 00:59:14 UTC
From: Whitebear1122
Topic: 11860 Message: 11866

Greetings 29'ers! It's time to dust off all those old chirpers and whooper transmitters and get them ready for this years installment of the Bruce Kelley 1929 QSO Party!! Last year Paul N1BUG beat the pants off of us with 87 contacts so I know there are a bunch of guys looking to beat Paul this year :) I do know there are a 29'ers who don't have to dust off anything because they use their 29 transmitters all year long like Harold KB0ROB and Dave WA8DOF. While I QSO all you 29 guys just once a year in the 29 QSO Party, when I hear your 29 station in the event, it's like hearing an old friend after all these years. I'm bummed when I can't make the QSO because it'll be another year before I have the next chance. I look forward to hearing all you guys. Thanks. 73, Scott WA9WFA

The 2015 Bruce Kelly 1929 QSO Party and W2ICE Special Event Station

The Bruce Kelly 1929 QSO Party is a yearly AWA sponsored event where participants build their own transmitters using the designs, techniques, and tubes that were available in 1929 and earlier, and then put those classic transmitters on the air and try to contact as many other 1929 stations as possible. Since they use early designs, it is a cacophony of whooping, chirping, buzzing, clicking, drifting, swishing, swaying, warbling, and other interesting signals. This is what ham radio sounded like in 1929 and for two weekends in December its 1929 again on the ham bands.

We will again be activating Bruce Kelly’s W2ICE callsign as a 1929 SPECIAL EVENT STATION for the 2nd year in a row! Last year I activated W2ICE from Minnesota for the first time since Bruce’s passing and I was told it was exciting for the 29’ers to hear and working the namesake station of this event! W2ICE is operating as a 1929 station and contacts count just like any other station. We plan to pass W2ICE portable to a different call area of the USA for 2015. I’m not telling you ahead of time where W2ICE portable will be operating from so it will be a surprise. The 1929 QSO Party was started in the early 1990’s and championed for a several years by Bruce Kelly W2ICE, an AWA co-founder. Prior to Bruce’s passing in 1997 he asked his close friend John Rollins W1FPZ to keep the 29 QSO Party going. John Rollins managed the QSO party for several years and renamed it the Bruce Kelly 1929 QSO Party in honor of Bruce. Eleven years ago John Rollins asked me to manage the 29 QSO Party for him and Bruce, and to keep the event alive because it meant so much to both of them.

Dates and Times: First two weekends of December, Saturday Dec 5 through Sunday Dec 6, and Saturday Dec 12 through Sunday Dec 13. Starts at 2300Z (6:00 PM EST) Saturday night and finishes at 2300Z (6:00 PM EST) Sunday night, both weekends.

Objective: Contact as many 1929 stations as possible. Contact exchange consists of RST, Name, QTH (State such as ME or MN or NY), last two digits of the year of the transmitters design or publication (such as 29 or 27 or 23, or pick a year if you’re not sure), type of transmitter (such as TNT or TGTP or MOPA or COLPITTS), and power input (such as 6W or 9W).

Rules: Transmitters must be 1929 or earlier types of self oscillators such as the Hartley, TNT, PP tuned grid tuned plate, MOPA, Colpitts, etc. No crystal oscillators. Tubes must have been available during or before 1929. Typical tubes often used are type 10, 45, 27, 211, 71A, 01A. Individual stations can be worked only once on each band over the course of

two weekends. You can use any vintage or modern receiver that you wish. The event is open to all 1929 stations including non-AWA members and AWA members. You are encouraged to join the AWA and support 1929 radio!

Input Power: Transmitters are limited to a power INPUT of 10 watts or less. However, to help make East-West contacts, power may be increased to 20 watts INPUT between the hours of 0500Z (12 Midnight EST) and 1300Z (8 AM EST). Note this is INPUT power. Power input is calculated by multiplying PA plate voltage x total PA plate current. Example: my plate voltage is 300 volts dc, and plate current is 30 ma, so total input power is 300 x 0.030 = 9 watts input. Stations running more power than this are considered “modern” for this event and do not count.

Frequencies: The QSO Party typically operates between 1800 to 1810 Kcs, 3550 to 3580 Kcs , 7100 to 7125 Kcs, plus or minus depending on QRM. 40 meter activity is up significantly because it offers both night time AND daytime propagation! So when 80 shuts down Sunday morning, I hope to see you on 40m.

Logs: Please submit your log so we can see who you worked and acknowledge your effort! Either electronically email your log to Scott at HYPERLINK "mailto:wa9wfa@..." wa9wfa@comcast.net or mail via post office to: Scott Freeberg WA9WFA, 327 Wildwood Avenue, Saint Paul, MN 55110. Logs must be in the 1929 QSO Party log format otherwise it will be difficult to score you. An official 1929 log sheet will be available for download from the AWA website. Please do not email logs to any other email address except to the WA9WFA account. Because of email problems in the past, I will acknowledge receipt of all email logs. If you do not receive an acknowledgement within a couple weeks, better check with me to make sure I received it.

Scoring: Remember that contacts with modern or high power stations do not count. Only count legitimate 1929 contacts. If you are contacted by a modern or high power station, be polite, mention the AWA QSO Party and point them to the webpage for more information, then move on, or QSO them if you wish. We will count contacts with W2AN, the AWA club station. Scoring is simple. Add up the number of legitimate 1929 QSO’s. Example: if you make 15 QSO’s on 80 meters,10 QSO’s on 40 meters, and 5 QSO’s on 160 meters, your final score is 30. All submitted logs will be scored and the results published in the AWA Journal. Please submit logs by January 15, 2016. 73, Scott WA9WFA

Hey Don -

I had some time today so I spent some of it up in my shack working on an antenna tuning project. I was listening to 40 AM in the background for entertainment, and, low and behold there you were. You called a guy in PA right after he finished his QSO on your DX-60. I think he was in Philadelphia. You sounded great at my QTH. Evidently much better than at his, as he said you were not too strong. Regardless you were booming right in here, and I am not far from the other guy, here on the Jersey shore. Good audio and good signal. I would have given you a call if my antenna tuner would have been on the right band, but, it was not. Just as well, because as soon as you guys finished, a real strong Chinese AM broadcast station took over the frequency. Maybe another day. 73 - Mike

Hi Larry:

I do have photos on the AWA site but I will put the latest and greatest here for you. The SS contest sounded like sheer pandemonium on the set but with neurlogical (neurotic? HI) filtering it was pretty easy to pick out signals. All in all the Eddystone-2015 is a hoot to use. Tube complement is a #32 detector and a VT-67 (a "militarized" #30)

The starting point for the grid coil is 60 turns on a 2.5” long, 1” dia form. That would put the winding pitch at about 1mm. Is that correct or am I missing something? All of the pictures seem to be close wound!

Greetings 1929'ers! I just finished hooking up the 29 Colpitts on 80 meters. Seems to be working ok. I haven't tried it on 40 m yet but it "should work". While setting up I heard W0VLZ testing around 3562 so I know Niel will be around tomorrow night.

80 cw stinks tonight with poor propagation. Niel was rough copy from just down in Rochester to St. Paul. The worse 80m is the more I count on 40m during the day. I probably won't be on 160 unless I get desperate. My 200' low inverted VEE is an NVIS so I'm lucky to work anyone in MN much less further out. In recent years 40 m has been good during the day.

Please remember that you can crank up the power at 0500Z through 1300Z so you should take advantage of that QRO.

Input Power: Transmitters are limited to a power INPUT of 10 watts or less. However, to help make East-West contacts, power may be increased to 20 watts INPUT between the hours of 0500Z (12 Midnight EST) and 1300Z (8 AM EST). Note this is INPUT power. Power input is calculated by multiplying PA plate voltage x total PA plate current. Example: my plate voltage is 300 volts dc, and plate current is 30 ma, so total input power is 300 x 0.030 = 9 watts input. Stations running more power than this are considered “modern” for this event and do not count.

73, Scott WA9WFA

Last year I had the pleasure of operating W2ICE/0 and that was the first time Bruce Kelly's call sign had been heard in the 1929 QSO Party since Bruce's passing. This year W2ICE will be operating from the East coast. As Paul has been hinting (hi hi) N1BUG will have the honor and pleasure of operating as W2ICE/1 this year. Paul was the winner of the 29 QSO Party last year. Paul's big signal should put W2ICE/1 in far more log books that I did last year. So thanks to Paul for helping us out by being the Special Event Station this year.
73, Scott WA9WFA

That's wonderful news. I had mistakenly inferred from one of Paul's earlier messages that he would not be operating in this year's BK...glad to hear I got it all wrong. Paul will end up with several pages in the log I'm sure!

73 Steve

PS...remember, NO 160m this weekend (ARRL 160 CW hasthe band plugged). We will have to figure out a watering-hole hour for our 160m ops next weekend. I know most don't like to spend too much time down there before scurrying back to 80m paydirt.

My annual plea / reminder for east coasters...please hang-in on 40m for a couple of hours before moving to 80m as it is still broad daylight back here when the BK starts. I can usually work the east coast on 40m about 30 minutes into the start and then for a couple of hours following sunset.

Scott,

Yeap, 80 seemed pretty dead but 40 does seem to be better...fortunately so since I have to crank my TNT output down to 1 watt (for 9 watts in) before I have a decent sounding signal on 40. But at 1 watt out the Reverse Beacon Network still copied me from VA to NV so there is hope.

Looking forward to working everyone tomorrow night.

73,
Niel - W0VLZ

Paul, I too really enjoyed finally having an "eyeball QSO" with N1BUG.
Truth be told, it was one of the main considerations tipping the scale
in favor of making the trek all the way to the Milo hamfest.

Yep, that's exactly what I observe here.

I "lost" one of my 71A's , so this year my PP-TNT will be sporting a
pair of 45's (again).

Sorry Steve, the prankster in me couldn't resist having a little fun with this. The BK announcement said the location of W2ICE was to be a surprise, and I knew the special event station isn't eligible to win the first place award. Hence, a little game of subterfuge on my part. :-)

I am very honored to have been chosen to operate as W2ICE/1 this year. The fact that my last name is the same as Bruce's (and even spelled the same) add a little something extra special for me. As I told Scott, I will do my very best to get into the logs of as many '29 stations as I can. Hopefully propagation will cooperate in this endeavor.

> We will have to figure out a watering-hole hour for our 160m
> ops next weekend. I know most don't like to spend too much
> time down there before scurrying back to 80m paydirt.

Yes. After 0500 would give us the option to run a little more power but is too late for many here in the east (not me!). Propagation even to the midwest probably hasn't settled down much before 0200 or so. I'm not sure what is best. If a time is chosen, I will be there. If not I will simply keep checking 160 and move there when I start hearing BK activity.

Right. I usually work VE7SL and KK7UV early, assuming propagation is decent. If not, I will hang for a while hoping to get you guys!

it's too bad we can't use 160 this weekend as condx were superb last night on the ARRL CW...had long runs with my 150 watts including a report from F5OHS! Managed all W1 states before 0600Z (10 PM local) but had all but RI before 0500Z. We can only hope that condx will be as good next weekend.

I always enjoy seeing pictures of everyone's setup, so here are mine for this year... a wide shot for perspective and a close-up of the BK rig. I wish I had space for a vintage-only station, but this small room must suffice for all radio operations (vintage, modern, lab, shop). Set up. Tested. Working. Let the fun begin! 80m coils shown but I will be starting on 40m.

Actually I sort of can on some bands but don't. Usually I put the key on a board across the arms of my chair. I moved the high back chair out of the way for the pictures and just set the key on the desk. I have tried keying the TNT with the key where you see it. On 160 there is little affect; on 80 it gets quite a bit more wobbly than you are used to hearing from me; on 40 it's a disaster!

Agreed. Congrats on F5OHS! That's a nice one from your QTH!!! After
a dismal start to the "season", 160 has been sounding good most of
the time for the past week to ten days. I hope it holds up for next
weekend. Last year conditions in the BK were just awful on all bands.

Thought I'd get an early start just to test the rig. I am on 7.110 now
and I'll keep sending CQ until the real thing starts.

So, guys... I hate to ask, but what is the consensus on using something other than a straight key in the BK? I've always used the straight key as it seems most period appropriate. But I've only been operating four hours (three if you deduct breaks) and my arm is killing me. Been doing a lot of hard physical work all summer and have sustained a few minor injuries to the arm in the process. Not that I can rig up anything else this weekend, but just curious for future reference...

It would be appropriate for “Bugsy” to use a “bug”. Bugs came into use right at the turn of the century, for telegraph stuff, however, by the 1920’s a lot of hams were using them and the bug manufacturers were then catering to the hams as well. A lot of early bugs would be time appropriate. 73 – Mike

Here it's 11:30 PM and I'm hearing VE7SL, W2ICE/1, K4JYS all about S4 to S-5. Just 15 minutes ago I was hearing VE3AWA the best I've heard him all night. Where are the all the other stations I wonder? Here is the time when we can crank up the power to 20 watts input, but no new stations.. Guess people are going to bed early in their old age. hi hi. I know I'm starting to poop out.

The Minnesota stations sound like ghosts to me, very weak, very watery, ethereal. I'm hoping 40 meters brings joy tomorrow afternoon.

I don't know Scott. This is the trend I see every time. After 0500z when we can crank the power up there are no stations left to work and very, very few even still on the air. Time to sleep and try just before sunrise.

Everyone is sounding a little watery here with the aurora, but signals are still reasonably good. I will be on 40 most of the day tomorrow.

This morning between working W1ICE/1 and W1ZB on 40M my receiver died. I was using my Softrock Ensemble II, and it's a hardware failure. Sensitivity is gone, I can receive my own signal but that's all. Once I figured out the RX died, I switched back to the R390-A, and was back in business. Bad karma for trying to use the SDR in the Bruce Kelley, I guess...

Well from back here, conditions were even worse than last year. Kind of a pity as conditions had been good all week and then suddenly took a turn just before start-up time, with K numbers climbing as hgh a 5 during the night. Many of the signals were sounding pretty auroral-like by 10 PM here. Oddly, the 160m band sounded terrific with strong signals from all call areas. Propagation can be such a mystery at times.

Just after my first 80m QSO, my new, never-really-used MOPA, started to go quirky. The oscillator was taking large frequency jumps and the power output was fluctuating with the frequency excursions. It took my a while to isolate the problem to something in the amplifier stage. My first thought was one of the old micas starting to fail so I unscrewed one side of several of them, one at a time, and jumpered-in a sub but to no avail. I eventually determined it was the grid leak on the amplifier gradually failing, in little 'jumps' at a time, eventually going from 12K to > 1M. I guess it didn't like the extra drive on 80m. Clipping in a 10K solved the problem but by that time (1.5 hours), conditions had become even worse. I sure hope the band recovers by next weekend.

Where were all of the MN guys...usually their signals dominate the band so either activity from MN has fallen or conditions were just that bad.

Paul and Larry were smoking in here on 40m once the sun had set...amazing signals at times from both of you. Never did hear Lou, but managed PA and NJ as well as ME on 80m.

I was generally pleased with the new MOPA, as it's frequency was rock-solid (other than the grid-leak meltdown) in spite of gale-force winds here again all night.

> I had a hunch about that Steve. ;-) Is that HV keying interface part

Paul - I took the easy way out and built this kit several years ago:

http://www.hamgadgets.com/UKA-2

It will key both + or - lines up to 400V, maybe more.

There are various homebrew FET style interfaces that should work just as well,,,here is one:

From: K3PID
Topic: 11958 Message: 11958

OK, got the TNT running but could only get a dip at 3980. Started adding turns to the grid coil and brought it down to 3750 before I realized that I had only wound 10 turns on the tank coil.... no wonder the tuning cap was fully meshed! Err... back to the hardware store for more copper tubing...

How stupid! Should have it working by next weekend... I hope!
Ron K3PID

11959. Well...

It looks like 45 '29 QSOs plus 3 modern stations in the log at this point. My arm and sending is getting a little better but the TNT needs service again. The bolt in the beehive insulator for the antenna coil is loose. This inevitably happens every time. I will have to remove the beehive from the base and tighten that bolt before next weekend. I wonder if glue or loctite would do any good?

Several stations couldn't hear me on 40. One or two couldn't hear me on 80. I tend to hear better than I get heard.

Being on the air with the old rig has me thinking MOPA again. Maybe this winter...? Nah. Well, maybe. Or I could finally build the receiver. No. MOPA!

Try an internal tooth lock washer Paul – between the nut and the lead washer on the topside of the beehive.. I say ‘internal tooth’ so the teeth aren’t visible and retain the 29 look.

Good point Larry. I also should note an exception for 40m after about 2100z. SSB takes over and I start giving reports like 379. On a couple of those I was exaggerating as 279 would have been closer to the truth. I don't know how those with non-directional antennas survive it. I'm listening on Beverages and still get killed by SSB from Europe and South America.

While playing in the BK yesterday morning on 80M (when the SDR was still working) I heard (barely) VE3LYX working someone. I think it may have been N2BE, but I didn't make a note of it. After that QSO was done I gave Don a call and he came back, but someone (a non-BK'er) with a strong signal stomped all over him. I sent a few QSY's which were either not heard or ignored by the offending station. Anyway, I was able to copy all of Don's info except his TX. When I asked Don for a repeat, propagation between us had completely disappeared.

I have talked to Don a few times on AM but never on CW until now.

Don, we'll have to try again next weekend. I didn't hear you at all on 40M, but I wasn't active from about 11AM-3PM local time yesterday.

From: N1BUG
Topic: 11966 Message: 11966

Thanks to Steve and Niel for links to HV keying interfaces. Much as I like to keep things 100% period correct, I think I'm going to get one (and a keyer! Mine is built into my main HF rig!). I would no doubt enjoy using the TNT a lot more if I could use a keyer with it. Between carpel tunnel and shoulder pain I was really struggling with the brass pounding Saturday night. I apologize for all the mistakes! It was a little better Sunday.

73,
Paul

11967. Proper Keying Posture

Yahoo group: AWAGroup (2014 — 2016)
Date: 2015-12-07 12:11:35 UTC
From: Steve Flood
Topic: 11967 Message: 11967

Five years ago I attended a centennial/commemorative event at a small local community. I there had the pleasure of meeting an elderly woman who was a Western Union telegrapher. She had a display of her tools of the trade and was demonstrating morse sending. After entertaining a few comments and questions as to whether her arm or hand got tired or sore, she replied adamantly "Not if you're doing it right!". She would then demonstrate the proper posture that allowed her to send for hours. That posture was NOT like seen in the classic young Sarnoff photo or military training video.

She advocated for sitting up straight in an armless chair, with your arm and shoulder hanging relaxed at your side. Then bend your lower arm at 90 degrees to the upper arm and allow it to relax into a natural position without trying to rotate horizontally to the side away from your body. (For me this natural position places my hand four inches above my right thigh.) She said "This is where your key needs to be". So I built a little slider shelf for my key that mounts under my operating table. That was great advice. No more arm/hand problems.

I didn't have any of that good posture stuff going in the shack this year. Typically I would duct tape the cw key to the stiff arm of my operating chair, and have room for my elbow to rest on the arm also. Chair broke this year and was tossed out. My "new" shack chair was thrown out of the den by the misses for looking to ratty so I snatched it and put it in the shack. The arm isn't long enough and is curved, so I had to set the CW key on a separate bench stool. No elbow support what-so-ever, so the cw wasn't quite a smooth as usual, and there is some hand fatigue.

Burt -

I like your antenna tuner. Do you have your inductors ganged? I just built one, however I turn my inductors individually on my first trial model. I also used a coaxial balun on my first unit, but, I did not like the performance that much. I had about 33 feet on a 5" diameter form. Just the other day I replaced it with a W2DU balun which consists of about 15 inches of RG-303/U and 50 ferrite beads made from 73 material mix. I attached a few photos of the original and the latest. Let me know if you have suggestions. So far it works from 160 through 15. I have not tried 10 yet. The antenna is a 290 foot long inverted V fed with 6 inch spaced homebrew line. 73 - Mike

Mike,

Yes, if you look at my QRZ photo, you can see the shafting and the 90 degree gearboxes so mine is connected in the back with gears. I think most guys use a ribbed belt affair but I had some Millen gear boxes so used them. I can tune 160 thru 10 meters and am using a 160 meter loop at My AWA station which is in a forest log cabin and it is run on batteries and an inverter. If the station is real weak, I listen on DC power only and turn on the inverter to transmit. Your set up looks fine but I would gang the inductors somehow. I have an inverted Vee I can use here as well. I think the length is about 250 feet on it. The apex is at about 90 feet and I feed it with coax and match it with a simple L-network tuner.

Burt –

Thanks for the info. Eventually I may gang the inductors, but for now just manually turn them to the same place as each is the same and each has a turns counter. They came out of the BC-191/375 transmitters. On some bands, specifically 160, it just seems that I cannot get any better than about 1.6:1. Most of the others I get 1.2:1. I have been used to link coupled tuners and was always able to get down to 1>0:1. What is your experience? Thanks – Mike

Mike,

If I take my time, I can usually get it down to 1.2 to 1 or so.
Maybe give some consideration to antenna length as it isn't very
close to your intended operating frequency. I would shorten it
up a few feet and see if the SWR is better as a test. You must
have a good reason for that antenna length that I don't know
about.

Hi Mike, Burt,

Could you guys describe the circuit you are using for your tuners?

My guess would be a balanced "L" network with the balun on the input
(low-Z side). Is that the configuration, or is it something different?

Larry –

You have it right. It is essentially the tuner AG6K made popular, http://www.somis.org/bbat.html . 73 - Mike

Larry,

I'm using the standard double L-network with the balun on the
transmitter side of the coils. If you look on the web you
can find the diagram. It's called the balanced balanced double L
by Richard Measures (AG6K).

Ah, yes. I've been to Richard Measures' (AG6K) several times in the past, great stuff. One project on my to-do list is a version of his hi-pot tester.

One of the tuners I use here is very similar: a balanced (double) pi network, but for most matching situations the input caps are 0% meshed, so could have gotten by with a balanced (double) L.

I do have a 0 to 30 KV HV power supply here at a few mills that does well for any Hi-Pot testing I may have to do, HI. Back in ’66 I worked for a transformer company and we did make some real big transformers. Our large Hi-Pot was in a large cage with numerous interlocks. BTW, heard you last night on the Gray Hair net. 73 – Mike

Burt –

I have no good reason at all for that length. It is 145 feet on each leg of the V of #6 solid copper. I figured since 130 feet was ¼ wavelength at 1.8 MHz a few feet longer should make little difference since I was using a ladder line feeder and on the higher frequencies it is several wavelengths anyway. Regardless, my original tuner was a link coupled one and I was able to get down to 1.0:1 on any frequency. The pain with that is all the taps when changing bands. That was the main appeal of the AG6K style tuner. 73 – Mike

Mike,

If I take my time, I can usually get it down to 1.2 to 1 or so.
Maybe give some consideration to antenna length as it isn't very
close to your intended operating frequency. I would shorten it
up a few feet and see if the SWR is better as a test. You must
have a good reason for that antenna length that I don't know
about.

Mike,

My Inverted Vee is #8 stranded wire cut to 1800 Kc and am using
RG-8U and no balun at the apex. For what it's worth I used #8 wire
only because I had a big roll of it. In the shack I use a simple
L-network made from some old Cardwell stuff. It works great.

Burt –

I assume you only use that on 160. My intent with the ladder line feed was to use my inverted V on all bands, and I have used this almost continuously since I put it up in 1995 at this QTH. The center was at the top of a 70 foot tower, guyed in 6 places at two different heights. I used #6 because I had it and because I wanted it to last. I had a pulley on top so it could be lowered to work on if need be. Well, I never had to work on it until Sandy. Even then the inverted V was fine. An ice laden branch weighing a ton fell from one of my trees and fell right on one leg of the V. Well, since I built the antenna so good it survived, but, it snapped the top 25 or so feet right off of the tower, which landed on the house and fortunately did not cause any harm. Just this summer I got the inverted V up again but now it is only at about 45 or so feet. Still seems to work out well enough for me. 73 – Mike

Mike,

My Inverted Vee is #8 stranded wire cut to 1800 Kc and am using
RG-8U and no balun at the apex. For what it's worth I used #8 wire
only because I had a big roll of it. In the shack I use a simple
L-network made from some old Cardwell stuff. It works great.

With Marty's agreement I am sharing his letter to me.

73, Lou

Lou,

Thanks for the e-mail, the picture of your station and your 1929 rig and for the QSO on 80 meters AWA BK event. I had a lot of fun. Your old receiver really looks neat. Must be an old National. I see you have a National speaker there as well.
You did beautiful construction work on your antique rig. Your signal was quite strong last night. I've included a couple of pix of mine. I'm not great at building (although I have built many projects over the years.) My Hartley has an old fashioned milliammeter on the rear edge fastened with double face tape. The quarter copper tubing came from Lowe's. I used copper flashing screwed to the wooden board with wood screws to try to give a low loss and low inductance connection between parts. I fashioned a lever made from plexiglass to move the output link (made with 2 turns of very stiff enameled wire) vertically in and out of the tank coil. I used all junkbox parts. My circuit came from an article by Scott Freeberg in a 2009 AWA Journal article. Mine has an input power of just a little under 7 watts using an old 27 tube. It was hard to get it to behave, but overall it was a very fun project. I started this project about 3 years ago and used it maybe 2 or 3 years ago for the BK event then. Over the past week I tried to re-do it it and make it better, more solid, less clip leads (HI) with the addition of the lever, the meter, the terminal posts on the back.
I powered mine using an octal plug plugged into the accessory socket of my Heath DX-60 B. I had to add a dropping resistor as the voltage was too high for the high voltage. I used a homebrew power supply sitting on my Heath SB-300 to provide the 2.5 volts for the filament of the 27 tube. I used Direct Current. None of the voltages were regulated and I was surprised it didn't chirp more. I keyed mine with an old Heathkit iambic keyer which was driving a QSK TR switch, a project designed by Phil Salas, AD5X, in the Feb 12 , 2012 issue of QST.
Thanks again, Lou. I'm only set up for 80 meters. I hope to build one for either 160 or 40 meters over the next year.

All the best and 73s, Marty, KK4RF

From: Roger Kuchera
Topic: 9796 Message: 11992

Gentlemen, I am trying to find out some information on a particular General Electric transformer. Not so muchit's specifications as they are marked on the transformer itself. It's an oldie. The markings are:

General Electric CG-301110

612-593-0-593-612 .213A .204A .204A .213A

The primary can be used for 220 or 110 VAC.

My concern/question would be to find out if it can be used with a bridge rectifier and capacitive inputfilter.

Looking around the net got me no where. Can anyone help?

My overall plan is to put some fire in my 860 PA stage.

Thanks in advance.

Roger/K1TG

I am sure I have some in the basement, but, finding any is another story. Would anyone have anything close to or similar to the dual Millen drive shown in the photo? It does not have to be a Millen and it does not have to be enclosed. It just needs to be a 1 to 1 dual 90 degree drive for my antenna tuner that I am playing with. Would be happy to buy or trade. 73 - Mike

I'm no expert but it seems I do recall reading something like that somewhere. I once had a transformer that had printed on it "Use choke input filter ONLY". I used it with a modern capacitor-only filter and it self destructed...

I suspect the vast majority of transformers don't care.

That seems like it was due to surge current rather than high voltage. Regardless of what it said, I bet the transformer already had an issue, like oxidized connections inside. Maybe for a certain application, for a certain output voltage, it was required to have a choke input. Also, it depends on the rectifiers if they can take the instant short of a cap input filter. 73 – Mike

That seems like it was due to surge current rather than high voltage. Regardless of what it said, I bet the transformer already had an issue, like oxidized connections inside. Maybe for a certain application, for a certain output voltage, it was required to have a choke input. Also, it depends on the rectifiers if they can take the instant short of a cap input filter. 73 – Mike Mike B. So, what would happen if you hooked it up to 220V, without a load? Would it break down? I bet the insulation in that sucker is more than adequate. I did work for a transformer company for a year in the mid 60’s and the only time we had a Hi-Pot failure was due to poor windings and never insulation. In other words a manufacturing problem. 73 – Mike

I suspect you're right about the failure mode, as it seemed to develop shorted turns - audible hum/vibration and high current draw with no load on the secondary. It was a NOS sealed type. I suspect it was potted, though I made no attempt to rip or saw it open after failure. The rectifiers and everything else survived, just the transformer went bad after some weeks of fairly frequent use.

Exactly. Shorted turns happen only due to either over heating or a manufacturing problem. Remember, there is very little HV difference between turns, or for that matter between consecutive layers. The only place insulation may matter is between the primary and the secondary layers, and as you all know from taking transformers apart, that arear is well insulated from each other. 73 - Mike

I put inrush current limiters on all my power xfmrs. It helps to reduce the surge current on start up.

That is probably not a bad idea at all Len. Although I believe the transformer Paul had a problem with probably already had some inherent problem. I only had a transformer problem once and it was due to my own stupidity. About 30 years ago I got into operating field day from home around midnight. So, by that time I was the new guy on the block and everyone wanted to work me. Well, I went about 3 hours straight and made about 300 contacts before all hell broke loose. It sounded like someone was firing a machine gun in my basement. My HT-33B linear blew its transformer. I loved that amp and it served me well for many years, at least 15 by that time. The problem, I stacked a bunch of big heavy books on top of the linear and forgot all about it. So, for that essentially continuous 3 hour operation there was essentially no air flow through the final PL-172 or the transformer. Talk about hot. The amp could barely be touched. I shut off the circuit breakers and went to bed. 73 – Mike

I got the idea for the current limiter from Fred Ware (I think) It not only softens the start up, but also drops the voltage a couple of volts closer to what the old transformers were wound for. So far, I haven't had a problem with overheating, but in the winter time the clouds settle down over the house and come in through the windows. Everything gets damp and sticky, and HV stuff starts arcing & shorting. Sometimes I can't get my computer monitor to light up until I blow some hot air into it with my heat gun.

12007. Transformer info addenda

Yahoo group: AWAGroup (2014 — 2016)
Date: 2015-12-11 18:28:21 UTC
From: Roger Kuchera
Topic: 12007 Message: 12007

Gentlemen, As I expected, I received a wealth of information re: my transformer. The capabilities of thetransformer are based on a complex set of parameters. A friend of mine in W7 land had thefollowing comment:
Well, it isn't rectifier that gives trouble, at least IMHO, it is the first capacitor. If that is "too large" (depends on the transformer) the peak voltages can get pretty "impressive".
I will be using 4 Aerovox (non-environment friendly) Pyranols rated at 10 uF/1500 V. in series-parallel as the input cap; followed by a 20 H. @ 300mA. choke; terminated with 500 uF/2500 V.The bleeder is a 25K/225 W. wirewound. All of this will hopefully keep things under control.Supplies of this caliber can get pretty ugly during the smoke and flame tests. I will be usinga Variac to bring it up initially.

I believe this transformer is a surplus item. When I cleaned off some of the crud, I found anumber of inspection stamps and an anchor with USN on it.

The upshot of this whole diatribe is; it should work OK.

Thus it should make my new 860 PA step and fetch it. :) :)

Thank you all for your help.

This is a military/industrial transformer. Just think all the stuff we did with transformers out of discarded TV sets of the 50's without any problems. I kind of disagree with your friend in that a very large input capacitor will result in a very large peak voltage. It will first have to charge to create any voltage. That time constant will be dependent on a lot of variables in the circuit, but, with a very large first capacitor it may be lots of milliseconds. In the meantime it will result in a large peak inrush current. I suggested you try putting 220 on the 110 input, preferably with a variac since your main concern initially seemed to be HV breakdown. Regardless, it sounds like you feel comfortable now to go ahead anyway. I personally do not see the need for a 500 uf on the output of the filter choke. About 50 should be more than enough. Besides helping with the filtering action, the output capacitor also helps with the dynamic regulation. Keep us informed on how it goes. Unfortunately the power supply seems to get the least attention in almost any system as it is assumed to be the simplest sub-assembly. This is even true of military designs, and in the long run causes the most problems. 73 – Mike

Subject: [AWA Group] Transformer info addenda

Gentlemen,

As I expected, I received a wealth of information re: my transformer. The capabilities of the

transformer are based on a complex set of parameters. A friend of mine in W7 land had the

following comment:

Well, it isn't rectifier that gives trouble, at least IMHO, it is the first capacitor.
If that is "too large" (depends on the transformer) the peak voltages can get
pretty "impressive".

I will be using 4 Aerovox (non-environment friendly) Pyranols rated at 10 uF/1500 V. in series-

parallel as the input cap; followed by a 20 H. @ 300mA. choke; terminated with 500 uF/2500 V.

The bleeder is a 25K/225 W. wirewound. All of this will hopefully keep things under control.

Supplies of this caliber can get pretty ugly during the smoke and flame tests. I will be using

a Variac to bring it up initially.

I believe this transformer is a surplus item. When I cleaned off some of the crud, I found a

number of inspection stamps and an anchor with USN on it.

The upshot of this whole diatribe is; it should work OK.

Thus it should make my new 860 PA step and fetch it. :) :)

Thank you all for your help.

Hi Roger et all, I believe that there are 2 issues involved with your plans. #1 is that some xfmrs reputedly may not be insulated to withstand the voltage, at the secondary winding center tap, that will be present, when a bridge rectification scheme is used. The center tap is normally at chassis ground potential, in the xfmrs' intended application, but will have a significant amount of voltage, on it, when connected to a bridge rectifier. The 2nd issue involves the much higher peak CURRENT (not voltage) that will flow, not only during initial power application, but during each and every 1/2 cycle of the rectified AC waveform. In a choke input type filter application, the rectified current flow is relatively evenly dispersed over the half cycle of applied voltage, whereas the current flow, in a cap input system, is sharply spiked, and most of the current flow occurs at the very peak of the voltage waveform (use Google for a better/more complete explanation). The high peak current inherent with a cap input filter causes increased xfmr heating (and probably core saturation), and prevents one from extracting the power handling capabilities of the xfmr, as well as a choke input set-up would. Thus, some derating would be in order, when a cap input filter is used, if the xfmr is to survive. I believe that 5 mfd, on each side of the choke, would be quite adequate (2 of 10 mfd in series). IMHO, the use of a 250 mfd output cap. is a recipe for problems. GL with ur interesting project & 73 de Ron n4gjv PS: All of this not withstanding, I used a lash up of 4 series connected ex TV power xfmrs, and a voltage doubler rectification scheme, to provide ~ 2.2 KV to my 4CX250 VHF power amps, a few years ago. The insulation, in these xfmrs was not designed to handle that much voltage! So, nothing ventured, nothing gained applies, if the xfmr can be considered as expendable! I hope that some of this sleep deprived babbling makes some sense!

Just a reminder for tonight's 160m operations. Consensus was to meet at 0400Z on the very low end of the band (~1805) for a short session and see who is about rather than just hit 160m at random.

Let's hope that prop is better tonight than it has been of late.

Hi Mike I appreciate your input, Thanks! I realize that with a capacitive-input filter the voltage stress is greaterthan inductive. I need the voltage to make my 860 sing for it's supper. Actually, I would have preferreda single or double L filter. I have a 5/25 H. @300 mA swinging choke to use on the input side. With adouble L, the voltage drop would be too much and estimate the output to be only 1KV. The 860 seemsto like a much higher B+. Maybe I should hunt up a different transformer. At the moment, nothing is castin concrete. Roger/K1TG

I play electric base - mostly blues, soul, and classic rock.

Jamie is a keyboard player and also does some guitar - mostly rock.

I'm was one of the lucky guys to work Ron You had a good signal over in MN. Yeah the CW nets start up on and off from now through 10 pm, and they just send on top of us. I worked two stations tonight, pretty slow. I missed W0VLZ although I called him several times. Heard and called K4LJH but didn't snag him either.

Sorry I missed you Ron! It's always rough going for the first few hours with all the traffic nets and ragchewers about, but settles down after about 10 PM. Of course, AWA stations have thinned out by then too, but it is easier to work the ones that remain.

Congrats on getting your rig up and running!

73,
Paul, operating the special event station W2ICE/1

Something WES going on where I was so after awhile I went up where Ron was 3565 and hung around for a bit. Heard - -GMS and a couple of others but couldn't raise them. Taking a hot toddy break right now. Might even raid the fridge. Bought a new recording stick so it is running when I am in the shack. I am going to try and stick around 3565. Seems like a reasonable spot. Anyway, plan is to hang on till midnite then pop in the 45 tube and work perhaps for an hour. Here's hoping. Well if you heard me I should be OK if conditions improve.

From: Whitebear1122
Topic: 12028 Message: 12028

Just worked W1ZB in MA so I know the band is kind of open for me anyway. Propagation is terrible tonight. I barely heard the Minnesota stations and worked 4 stations tonight. Part of MY problem was that I didn't realize my SWR was high. Reflected was as high as Forward. Oops. I missed several stations due to that.

I plan to crank up the power at -0500 so I hope to work you.

I heard VE3AWA on and off over the evening so Lou was a regular. Heard W2ICE/1 for a while but signals were very low. Even Harold KB0ROB who is usually a big wheel was down in signal strength.

I hope to work a few more tonight.

KK7UV and I were asking the same thing last weekend. Perhaps BK activity is just way down from normal...surely it's not just condx?

My usual 6 or 7 MN stations (always dominating the band) are AWOL, with just three in the log and they were a struggle.

This is the only rig I am running this weekend. Just switched back to Low power at the top of the hour but before 8 managed to snag two. Band opened up for about 12 minutes then shut down but I had my info and QSL.
This rig is a Hartley and I run with a 45 tube or a 01A. It makes just under 7 w with the 01A and just over 16 W with the 45. This particular 45 draws heavy current to I am going to keep it in a safe place. I don't know what is wrong with it but i like it! The base is a Rat Trap which the company assures me is unchanged in design since the 1880s so it is period correct. The Key is a mouse trap of the same design reworked to function as a key. The rig works pretty hard on the 45 but it does the job well. Also does another mode well but we will save that for another QSO party. Taking a break. Will be back on this afternoon. When the band is open it sure is fun!

12043. 29 rig tone

Yahoo group: AWAGroup (2014 — 2016)
Date: 2015-12-13 14:23:23 UTC
From: Doug Forbes
Topic: 11882 Message: 12043

All four of my 1929 transmitters sound as if they have 60 Hz modulating the CW note monitored on local receivers. The power supply is regulated and I have tried DC on the filaments with no change. The ripple on the HV is less than 1VP-P. I have run them with no antenna so minimum loading and while the hum is less, it's still there. I notice also that the few stations I heard or worked had at least some of the same problem.

Ideas for Remedies ?

Hi Doug,

I sure was looking hard for you last night and this morning in the BK but no luck.

I had the same issue recently but my problem was the AC filament pair sharing the same cable bundle as my HV pair. Separating them reduced the AC hum modulation quite a bit. With your filament running DC, I might suspect whatever ripple is left on HV line might be enough to modulate it. Otherwise, VE7SL suggested that if your monitoring your signal with a speaker, perhaps there's some shock-modulation going on with your tank coil.

Steve, KK7UV

From: Ron Barlow
Topic: 11882 Message: 12045

Hi Doug, The hum that you are hearing may be a local phenomena caused by RF reaching the various power supply rectifier diodes. These diodes become "mixers", imposing 60 hz sidebands on the RF signal, before the latter is re-radiated by the power supply wiring. The addition of a .01 mfd ceramic cap across each and every one of these diodes usually effects a cure. A distant station will not hear this modulated sig, due to the relatively poor transmitting "antenna" (the power supply wiring), but your local signal can sound horrible. It can be absolutely maddening! A similar situation can happen with a receiver, when the conversion LO signal or the RF from an oscillating regen detector reaches the power supply rectifiers. Note that the diodes need not be part of the transmitter or receiver itself, but could be a part of some piece of other nearby equipment. I try to remember to add a .01 cap across all rectifier diodes and zener diodes as a precaution, to avoid this issue. 73 & GL de Ron n4gjv

Doug - would you like to have a try this afternoon, say around 2230 on 7105 +/- a couple?

>The ripple on the HV is less than 1VP-P. > > Ideas for Remedies ?

I was able to reduce this AC modulation quite a bit on my new MOPA. I added another .01 disc ceramic right at the Fahnestock clips across the B+. I was surprised that it made a difference. As well, I wrapped both the keying leads and the B+ through large #43 ferrite cores. Both measures helped considerably.

I asked a similar question a few weeks back and got no answers or replys. So I have been working hard on the problem. Rons tips are excellant. By pass everything I found to help huge. I stopped using power chokes, in fact removed them from supplies I had them in. I install a small ohmagehi wattage resistor at the beginning of the rectifier chain. I run perhaps one more set of diodes in series then technically called for as I dont want any to be near their max operation voltage.. And I have on a few sets installed an extra filter cap or caps with series resistors right at the set itsself. Is it perfect? No but it is a lot better then before I did this. More and more I think solid state rectifier supplies have issues tube rectifier supplies don't have. Do everything that has been suggested and if you find a magic bullet I for one will be most interested.

12061. BK de W2ICE/1

Yahoo group: AWAGroup (2014 — 2016)
Date: 2015-12-13 23:54:47 UTC
From: N1BUG
Topic: 12061 Message: 12061

I had a lot of fun operating the special event station but I am concerned that I let some people down. In my excitement to accept this great honor I failed to consider how tired I am after the events of the last several months or the strain on an arm that had preexisting issues. I had to take more and longer breaks than usual, and my operating wasn't as sharp as it should be. I need to count again but believe I ended up with 65 valid BK QSOs plus three modern stations in the log. This is lower than my usual count. My apologies to anyone I missed.

Conditions seemed good the first weekend but some of the regulars were not heard here. The second weekend didn't seem as good. I didn't hear any 7s or VE7s the second weekend with one exception. I only managed four QSOs on 160 meters. Nothing beyond Minnesota, though I did hear KK7UV on 160.

It wasn't until Sunday morning the second weekend that I realized I was getting on frequency the hard way! I had a method I had used previously, but had forgotten it! I use the control on the TNT for a coarse adjustment (naturally it has a very fast tuning rate) and then fine tune using the condenser on my OT antenna coupler. This works great, and since the sweet spot for power transfer is very broad there is no ill affect. Of course this method won't work after I build the next stage and the rig becomes a two board MOPA!

By next year I will have a keyer that can be used with the '29 rig. For me using a modern keyer will detract from the '29 spirit and experience somewhat, but better that than kill my arm operating I guess.

Meanwhile I am getting antsy to get the PA stage built. It has been too long on the drawing board. So has the receiver. Hopefully things are about to slow down here so I can get started on the PA.

Oldest rig worked: 1922
Lowest power worked: 2W

73,
Paul

Paul, you were awesome! Thanks so very much for taking the mantle this year and running W2ICE. 65 valid QSO's is far better than the 43 some I did last year as W2ICE/0. Thanks again. I briefly heard you this afternoon on 40m called a couple of times with no luck. 40 m seemed to have pockets of propagation. I'd hear an East Coast station, wait my turn, and they'd fade out before I could work them. I saw that several times. 73, Scott WA9WFA

Considering conditions Paul, I would say you did an exceptional job! I heard you briefly on 80m this morning but nothing like in previous BK's. The hotspot for me seemed to be just a bit further south of you...NY,NJ, PA. I only heard one station on 160, KK7UV.

Go soak that arm!

I was worried we were not going to make it then I heard you and waited till you signed. You were really strong here. I thought the rx would come off the shelf almost. That TNT has a nice sound to it. Thanks. I think we finished with roughly 7minutes to go. Glad it worked out. Is that the TNT that does phone as well? My Rat Trap does and quite well too. I would also like to work you CW with my 211A Hartley sometime when the dust settles.
The 199 tube for the new rig has been shipped he tells me so should be here in a day or so. They come from this side of the border (Nova Scotia). I am anxious to see if my Colpitts lash up will actually run. I never did a Colpitts before. Anyway although I am no competitor I really enjoyed the BK. Thanks to all who worked me or tried. I love running ""The Trap"

12069. 2015 BK Report de K4JYS

Yahoo group: AWAGroup (2014 — 2016)
Date: 2015-12-14 14:04:15 UTC
From: Bill Stewart
Topic: 12069 Message: 12069

Hello all BK'ers and interested readers,
This was my 13th consecutive BK...no bad luck and it's still a lot of fun.
The Hartley worked on 80 & 40m without a hitch, the '24 Meissner made
three QSO's on 160 and I used the TNT for over a dozen contacts on 80m.
So equipment wise..no problems. Band condx for the first weekend were
not too bad and made a goodly number of contacts. Forty, as usual, down
here, was trashy...lots of SSB and digital crap. And 80 meters was pretty good.
The second weekend, condx were not near as good. Had a lot of QRN and
band noise...not overly strong, but enough to make copying some of the weak
signals pretty rough.
Some of this years Highlights:
-Worked VE7SL on 80 & 40.
-Worked KK7UV on 80 & 40...tnx to both of the Steve's.
-Worked W2ICE/1 on three bands...tnx Paul for a job well done.
-Worked W8AU using his ORIGINAL '29 TNT...congrats Perry.
-Worked the elusive VE3LYX on 80m...almost made it on 40...great to work you Don.
-Heard Jim, W8KGI on 40 with a good sig...but he couldn't hear me.
-Worked Steve, N8YE with his Ford coil powered '25 TPTG...always a treat to hear.
-Worked good friend Ron, N4GJV on three bands.
-The NE1S TNT on 40m had one of the prettiest notes..neat T9 whistle, Larry.
-Worked N3TE in his first BK...holy cow, another Steve.
-Worked Mike, WU2D using his '22 Meissner.
-One of the greatest highlights and pat on the backs goes to all the BK'ers with the
great ears. Boy, some of the reports I gave and received were in the 33 to 44
range. And I guess the prize would go to Burt, KB0MM for our 160m contact.
He gave me a 229, I gave him a 339....and we made it!!

Thanks to Scott, WA9WFA for his hard work on keeping the BK running smoothly.
And also thanks to all who pulled me thru once again. What a great bunch of first
class operators.

Thanks Scott and all for the kind words. Scott, I heard and called you on 40 also. I guess it just wasn't meant to be.

I neglected to mention that local friend Ben, WA1PBR, who has quite the collection of antique radio stuff including a rotary spark gap and original motor that I am constantly lusting after stopped by the other day and was intrigued to learn that W2ICE/1 was on the air almost within stone's throw of his house. Ben had the pleasure of meeting Bruce years ago.

I also very much enjoyed my final BK QSO with Perry, W8AU, who said Bruce was a friend and who was using an original TNT! I join Lou in saying I would love to see pictures of that rig.

Doug, don't know if it was mentioned, but I found on my Hartley that
tweaking the antenna tuning &/or coil tap would make my raspy note
...about a T4-5 on 40m, improve slightly to about a T7. On 80m the note
is about a T8. In my case, the TX is mounted about 6 inches above the
p/s and the 210 is just above the pwr xfmr....don't know if some hum
is being induced into the tube, but will have to check that.

Catching up... sort of

wonder if glue or loctite would do any good?
Try an internal tooth lock washer Paul – between the nut and the lead washer on the topside of the beehive.. I say ‘internal tooth’ so the teeth aren’t visible and retain the 29 look.

Perhaps the lead itself would help some?... if I was using any. Those 'hives are slippery devils. :-)

I heard Joe. Recognized the call from my 80M AM ops using my ARC5 testing with Dave while Joe was I believe NC. I believe I have his TNT recorded. I haven't played it all back yet. I went back to him with my Trap Hartley but couldn't make it work. BTW Went Antiqueing today with the XYL and friends. I told her on the way over this morning if you ever see a telegraph sounder let me know. I want one. Last store I was in down in "The Valley" I bought a real good Brunnel Sounder for $50. I don't know if that is good or not. Doesn't matter really. It was for me in budget. Also got an old pair of National Earphones made in Toronto. (So was I "made in Toronto") Hopefully they are older then I

As I mentioned I bought what I thought was a Telegraph Sounder yesterday while antiquing in The Ottawa Valley. I had thought I could rig it up for a relay to use on my old rigs so I wouldn't be keying a long HV line out of an oscillator. Turns out what I bought was a relay AKA a repeater (I never knew there was such a device) so after a minor wiring repair I did a clip lead lash up to a 6 volt battery and put the Key line for the TNT on the relay contacts. It worked right away but my TNT was acting stupid this morning. (Probably exhausted from the first BK day) I had sent a series of Vs and IDed. I decided to quit and see why but I got a call from AA3EJ saying VE3LYX pse rply so I did. It wasn't much fun I am sure as the TNT was being bad but we did finish. So there first contact with my Telegraph relay running the key line. Now I have to see what is bothering the TNT. It was acting stupid on the straight key too.

Not at all! The mechanical arrangement can be anything you like. You are just required to use a transmitter circuit existing in 1929, excluding xtal control, tube type(s) available in 1929, and abide by the power limits. Go for it!

Topic: 12090 Message: 12090

I'm always impressed with the number of Qs I see from others in the BK. I had fun, learned some stuff and made a few contacts along the way...four here in MNplus Paul, W2ICE/1 usingmy push-pull 210 TNT at 6-10 watts on 80.

I had trouble with my antenna the first weekend (my fault). I had added a 20 mtr wire that made it ultra sensitive to wind. See http://w0vlz.blogspot.com/2015/12/a-winter-vertical.html. The second weekend I had five Qs before my transmitter started acting up. Every minute or so it shifted frequency and then popped back on frequency. Listening to it, it sounded like a character is being dropped. The problem showed up with both the antenna and the dummy load and different tube sets. I suspect a bad (arcing?) variable cap but time (and debugging) will tell.

Niel - W0VLZ
(now looking forward to the LC)

I made a vernier using a trick Lou showed me. He had a rubber grommet of some type on a screw close enough to the dial outer face to drive it. I tried it on my 01A hartley from last year using a rubber bushing from an AC Dc radio variable capacitor mount. it worked very well SO I took it a step further. On my 211A hartley I had a 4 inch dial plate I made from That hard plastic that used to face 1920s neutrodyne radios. (Could have used anything) I fastened the plate (with three screws) to a normal knob and mounted it in the tuning cap shaft. I went to Lowes and bought a grommet in the unusual hardware section near the science projects drawers. And I bought a 1/4 inch diameter Nylon Space. I shoved the grommet on the spacer and gave it a bit if rubber cement just before positioning it to make sure it didn't slip. I held it to the dial plate making sure the gromet was firmly against the plate and used a drill bit to register the hole. I drilled the hole. I made sure the head of the screw was smaller then the 1/4 inch spacer and then installed the whole assembly tightening until the spacer was positioned well but still turned freely. I installed a old early radio know. In fact one of the ones Lou gave me several years ago. I now have a very smooth working vernier or friction drive reduction unit that cost little and works very well. If you mount the assembly low so it is below where the variable cap is behind the panel you may find hand capacity trubal is greatly reduced.

I had my TNT going yesterday and had a similar problem. I traced it to a poor contact with the Variable Caps rotor wiper. I had already made an addtional contact for it but obviously need to redo it. If I swing the cap back and forth before tuning the rig works fine so i am pretty sure that is the trouble. It will be in the rig hospital today and I will find out for sure.
Really enjoy your blogging!

I have a significant hand capacity effect on the PP-TNT, where the frame/rotor of the condenser is connected to one end of the tank coil (the stator, of course is connected to the other end). A few years back I added a mechanical friction-drive vernier with an additional 1/4" shaft and grommet. The groove of the grommet rides against the rim of the tuning dial. I made the shaft about 3" long so that I could keep my hand farther away from the condenser while tuning. It reduced, but did not eliminate, frequency pulling due to hand capacity.

OTOH, the Hartley has absolutely NO hand capacity effect, and the rotor is connected (for RF) both to the grid of the 841 tube and a period APEX metal vernier tuning mechanism. So it's also "hot" for RF, but still no hand capacity. Go figure. Can anyone explain this?

Is this your Hartley configuration still? Isn’t that a shaft insulator between your Apex dial and the rotor? Perhaps the insulator and the few inches spacing from the tuning knob to the rotor plates provides some decent shielding from hand capacity. The Hartley in my MOPA rig is similarly insulated, although not as well as yours, but the hand capacity is far less than the direct connections on my TNT and Hull Hartley.

Hi Steve,

For some odd reason the image didn't come through here, but I just went downstairs and checked. You are absolutely right, I DO have an insulated shaft coupling between the tuning dial and the condenser shaft, and, furthermore, the dial is grounded. It has been so long since I built the Hartley I had forgotten. Thanks, mystery solved!

I'm disappointed another BK has passed without you in my log. I hope to run the Hartley and TNT in the Linc Cundall, perhaps we'll have another chance then.

12100. Re: [AWA Group] Opinion needed

Yahoo group: AWAGroup (2014 — 2016)
Date: 2015-12-16 15:54:05 UTC
From: Larry Szendrei
Topic: 12086 Message: 12100

I'll keep the subject line, "opinion needed," because it still works.

I have come to the conclusion I fried my Softrock Ensemble II SDR with RF (2W out from the TNT on 40M) during the BK. I had thought I had wired the TR relay at the operating position I was using to ground the RX antenna input during transit, but when I attempted to verify it with an ohmmeter after the damage had been done, it was not so. So either my memory is faulty (like it was with the insulated coupling shaft on the Hartley), or the relay contact is dirty. The relay is buried in a multi-purpose box with several cables going to it and is not easily accessible, so opening up and checking visually will be done later.

So, I contacted Tony (the guy behind the Softrocks) and he thought I had probably taken on the FST3253 IC which switches between 4 bandpass filters on the antenna side of the RX. My friend Bob N1XBM who is good with installing (and removing!) surface-mount devices came over Monday night. He replaced that IC and the SDR works again.

So I want to add input protection on the SDR (AND fix the TR switching so that the RX input is shorted out on transmit - belt and suspenders). I know that simple diode clippers will create IMD products with strong signals coming in on the antenna, and I've heard PIN diodes are better in this regard than regular small-signal switches like the 1N914, although I don't know exactly why. I also know that HV rectifiers are constructed like PIN diodes and are sometimes used as such at HF, and they would be more robust (i.e., handle more current) than the small-signal switches. Yesterday I played with back-to-back 1N4007s at the antenna input. With two diodes in an anti-parallel configuration I definitely had some nasty IMD products close to the center frequency when the diodes were in place. I added another diode in series with each one to double the clipping voltage, and that eliminated the IMD, and the presence of the 4-diode series/parallel network seemed completely transparent, even to the stronger signals on the bands. All this was done in clip-lead test mode.

Then I hooked up the 4 diode network across the RF input to my HP 410 VTVM, with a wire antenna also connected to the HF probe, and transmitted (through another antenna, of course) signals on 40M and 10M with about 40W. The diodes limited the voltage at the RF probe to about 0.3V in both cases (although I was expecting more like 1.4V = 2 forward junction voltage drops), in fact, the RV voltage at the probe actually decreased slightly when I keyed the transmitter. Without the diode network present I read greater than 1V just from ambient RF (i.e., when I'm not transmitting) at this location with the antenna connected to the probe.

So, for those of you who have knowledge in these areas, does this all sound reasonable? Is the 1N4007 an appropriate device for this application? Why are PIN diodes preferable from an IMD viewpoint in this application?

In any case I will put an SPST switch in series with the diode clipper so that I can enable and disable it at will.

Heck, I'd be OK with 50W DC input for all stations! That would still limit the RF power output to the 5-20W range from an oscillator directly coupled to the antenna. Put those 203s and 211s to work! The MOPAs could put out up to about 35W for an efficient design, but their sigs tend to be better-behaved.

I think the main reason for the low power limitation was to keep a "low profile" on the bands so that we didn't draw unwanted attention with our less than squeaky-clean, unstable sigs.

Just a few remarks on the BK from out here in New Mexico.

First off, I had the flu the first weekend, so I definitely did not get on the air. So much for the flu shot this year! My wife came down with it a week later and is still getting over it! The second weekend was busy with all sorts of Christmas preparations, so I could steal only about an hour for BK activity on 40. Perhaps we could schedule another BK outing at some time when there are not as many other conflicting activities?

As to keying a TNT with an old telegraph repeater relay, I'd suggest putting an ohm meter across the relay contacts and confirming that the contact resistance is low, stable, and repeatable. Anything less would certainly reflect in the performance of the transmitter. If the relay contacts need cleaning I'd suggest starting off with something mild, perhaps DeOxit, sprayed onto a paper towel and worked across the contacts while the relay is energized. the very last thing you want to do to relay contacts is to go after them with an abrasive, like a file for instance. If there is precious metal on the contacts, silver for example, filing them may well wear the precious metal completely off. At most I would use some very fine grade sand paper wetted with a contact cleaner.

I key my MOPA with two relays, driven differentially so that I turn the oscillator on first and then the amplifier. The relays are in the filament transformer center tap leads - I have separate transformers for the oscillator and amplifier tubes.

And I accomplish "fine tuning" on my 210 Hartley with a small variable cap, vintage of course, in parallel with the main tuning cap. I also use several inches of fiber rod between that cap and it's knob to minimize hand capacitance.

73,

Jim Hanlon, W8KGI

I would think that PIN diodes would just be faster and maybe not have the square law characteristics of signal diodes, which probably does cause most of the IMD. While it would take more diodes, would it be possible to try and place diodes after each filter? This should cut down the aggregate RF at the input. Is there a switch on both the input and the output of each filter section? 73 – Mike

Subject: Re: [AWA Group] Opinion needed

I'll keep the subject line, "opinion needed," because it still works <mailbox://Users/Larry/Dropbox/Falcon/i7r33qrj.default/Mail/pop.myottmail.com/Drafts?number=46459&s=97359714/grpId=39470910/grpspId=1705063108/msgId=12097/stime=1450272240> .

I have come to the conclusion I fried my Softrock Ensemble II SDR with RF (2W out from the TNT on 40M) during the BK. I had thought I had wired the TR relay at the operating position I was using to ground the RX antenna input during transit, but when I attempted to verify it with an ohmmeter after the damage had been done, it was not so. So either my memory is faulty (like it was with the insulated coupling shaft on the Hartley), or the relay contact is dirty. The relay is buried in a multi-purpose box with several cables going to it and is not easily accessible, so opening up and checking visually will be done later.

So, I contacted Tony (the guy behind the Softrocks) and he thought I had probably taken on the FST3253 IC which switches between 4 bandpass filters on the antenna side of the RX. My friend Bob N1XBM who is good with installing (and removing!) surface-mount devices came over Monday night. He replaced that IC and the SDR works again.

So I want to add input protection on the SDR (AND fix the TR switching so that the RX input is shorted out on transmit - belt and suspenders). I know that simple diode clippers will create IMD products with strong signals coming in on the antenna, and I've heard PIN diodes are better in this regard than regular small-signal switches like the 1N914, although I don't know exactly why. I also know that HV rectifiers are constructed like PIN diodes and are sometimes used as such at HF, and they would be more robust (i.e., handle more current) than the small-signal switches. Yesterday I played with back-to-back 1N4007s at the antenna input. With two diodes in an anti-parallel configuration I definitely had some nasty IMD products close to the center frequency when the diodes were in place. I added another diode in series with each one to double the clipping voltage, and that eliminated the IMD, and the presence of the 4-diode series/parallel network seemed completely transparent, even to

the stronger signals on the bands. All this was done in clip-lead test mode.

Then I hooked up the 4 diode network across the RF input to my HP 410 VTVM, with a wire antenna also connected to the HF probe, and transmitted (through another antenna, of course) signals on 40M and 10M with about 40W. The diodes limited the voltage at the RF probe to about 0.3V in both cases (although I was expecting more like 1.4V = 2 forward junction voltage drops), in fact, the RV voltage at the probe actually decreased slightly when I keyed the transmitter. Without the diode network present I read greater than 1V just from ambient RF (i.e., when I'm not transmitting) at this location with the antenna connected to the probe.

So, for those of you who have knowledge in these areas, does this all sound reasonable? Is the 1N4007 an appropriate device for this application? Why are PIN diodes preferable from an IMD viewpoint in this application?

In any case I will put an SPST switch in series with the diode clipper so that I can enable and disable it at will.

Hi Larry,

In the old days (1980s-90s :) we used 1N914/1N4148 diodes as front end protection. I did experience some nasty IMD problems on occasion.

This is probably not what you're looking for but I now use something like this and have not had any problems (hopefully this link will go through)

http://arraysolutions.com/images/AS-RXFEPdatasheet.pdf

During the BK I use Beverages for receiving, running through a unit similar to this into my very modern receiver. I run the TNT into my various transmit antennas which are in very close proximity to some of the Beverages. This would worry me greatly if I didn't have the receiver protector in line. I have not had any problems. After the 2014 BK I cranked up the B+ to see what the old UX-210 could do if pushed. With 20 watts out I still had no problems. In reality I suspsect I could run a kW and be safe. Yep, the TNT survived that test, too. :-)

Do you recall the voltage, Paul?

Yes, Lou. 800V at just over 60mA. I had the antenna coupled more heavily than one should, so note was about T6 or T7 (similar to how I sound during the BK with 300V and overcoupling. :-)

On the other hand, I can get a real nice sounding 10 watts out if I mind my manners with that antenna coil!

Paul

Yes, I see the problem. If I had a block diagram it would have helped. Probably should have looked it up. So, I assume you blew the first switch with the RF and it is the one seeing all of the input BW to cause the IMD with the diodes in front of it. Of course if you are going to pump a few watts into it the diodes would probably not have helped anyway. Fix the T/R switch and forget the diodes, HI. 73 – Mike

The use of telegraph relays and sounders by hams were in style in the late teens and early 20’s. They were often modified to use silver dimes in the contacts to make, remote and safe high current keyers for spark equipment. They were even modified at times to make antenna changeover relays. 73 – Mike

AWA Linc Cundall Memorial CW Contest

Dates: Wednesday, January 13, 2016 @ 2300 GMT to Thursday, January, 14, 2016 @ 2300 GMT
And
Saturday, January 16, 2016 @ 2300 GMT to Sunday, January 17, 2016 @ 2300 GMT

Bands: 160, 80 and 40 Meters.

Download MS Word Log Sheet
Send logs to:

Tim Walker
19 Woodsied Ave.
Westport, CT 06880

All radio amateurs may participate and submit logs and all are eligible for an award. Non-member stations using pre-1950 gear count. All stations must submit logs to be eligible for an award and are encouraged to send a shack JPEG showing their vintage station. Electronic format such as EXCELä or (PDF, JPEG) scans via E-mail are accepted. Use the format posted on the AWA Site. Logs are due four weeks after contest. Plaques are to be awarded.

Objective: Contact the greatest number of AWA members or participating stations using pre-1950 design gear. The E-W multiplier has been dropped this year so all are on an equal footing. The 4 power levels have been retained. 20M has been dropped and the 40M frequencies have been shifted up slightly to the old novice band where slow CW is emerging again. When calling use “AWA AWA de W3GMS” for example. On contact, exchange the signal report, the year of equipment such as “TX36” for a 1936 transmitter and “RX 34” for a 1934 receiver. Send “MOD” for modern (after 1949) gear. And finally send your Input Power such as “10W”. Also send name and State or Country.

Frequencies: 1800-1820, 3550 – 3580, 7100-7125 kHz, +/- QRM Concentrate 160 meter contacts on the hour.
Equipment Multipliers MOD TX and RX 1
OT TX or RX 2
OT TX and RX 3

Power Multiplier 0 – 10 Watts Input 4
10 - 75 Watts Input 3

75 – 150 Watts Input 2
150 + Watts Input 1

N2BE contacts WT2W
N2BE Stn. Jones P-P at 6 Watts, Heath HB-10 (One OT), 1 MOD for 2 points
Power Multiplier for 6 Watts is 4
2X4 = 8 points

But, I didn't pump a few watts into it. The few watts were (mostly)
going into the antenna. The only RF getting into the receiver was due to
capacitive coupling, a few pF at best, across the antenna relay contacts.

> Fix the T/R switch and forget the diodes, HI. 73 – Mike

AS an old tune up man from the dark ages I have the proper tools for dressing relay contacts like found in electromechanical voltage regulators so that is here a non issue. Also have the ability to re-sliver contact points if required. It actually now does a very nice job of keying the TNT. I am as I said a bit surprised at how well it works. I was worried about arcing etc but watched it for quite awhile today while in QSO. Seems good but I will keep a close eye on it anyway. Just in case. I am going to leave it on the TNT. I do not wish to use it on Big Bertha because the voltages exceed 600 and that would be asking too much. I even tried it with my 1923 Vibroplex and it could handle it. I guess they were designed to sit unattended in a wooden shack in the middle of nowhere (one relay or repeater every 75 miles) and run flawlessly for years on end. Mr Bunnell did a great job I think.
donVE3LYX

Just a few remarks on the BK from out
here in New Mexico.

First
off, I had the flu the first weekend, so I definitely did
not get on the air. So much for the flu shot this year!
My wife came down with it a week later and is still getting
over it! The second weekend was busy with all sorts of
Christmas preparations, so I could steal only about an hour
for BK activity on 40. Perhaps we could schedule another
BK outing at some time when there are not as many other
conflicting activities?

As to keying a TNT with an old telegraph
repeater relay, I'd suggest putting an ohm meter across
the relay contacts and confirming that the contact
resistance is low, stable, and repeatable. Anything less
would certainly reflect in the performance of the
transmitter. If the relay contacts need cleaning I'd
suggest starting off with something mild, perhaps DeOxit,
sprayed onto a paper towel and worked across the contacts
while the relay is energized. the very last thing you want
to do to relay contacts is to go after them with an
abrasive, like a file for instance. If there is precious
metal on the contacts, silver for example, filing them may
well wear the precious metal completely off. At most I

would use some very fine grade sand paper wetted with a contact cleaner.

I key
my MOPA with two relays, driven differentially so that I turn the oscillator on first and then the amplifier. The relays are in the filament transformer center tap leads - I have separate transformers for the oscillator and amplifier tubes.

And I
accomplish "fine tuning" on my 210 Hartley with a
small variable cap, vintage of course, in parallel with the main tuning cap. I also use several inches of fiber rod between that cap and it's knob to minimize hand capacitance.

73,

Jim Hanlon, W8KGI

Hi Niel, I have noted that one common cause of the problem that you describe, is an oxidation problem at the rotor wiper, of any variable capacitor, that is included in the oscillator tank circuit. I have never used De-Ox (I believe that is the correct name), but I have read many raves about its effectiveness. I have not always experienced success when attempting to use other brands of contact cleaners, to de-oxidize variable cap rotor to wiper contact surfaces. In one particularly stubborn case (a BC-453), I had to physically remove the rotor wipers, so that I could scrape away the oxidized metal, at the rotor contact surface, to effect a cure of the frequency jitters. Repeated attempts to do the job, with the contact cleaner that I had on hand, were unsuccessful. I believe that the power oscillators that we use, are particularly vulnerable to problems, in this area, due to the relatively large amount of circulating RF current, in these high "C" tank circuits. From: Mike Feher
Topic: 12128 Message: 12128

Interesting you would bring this up Ron. There was just a discussion about it on the MRCA reflector and a week or so ago I inquired about the same thing on the 160 meter Monday AWA net run by Joe, N3IBX. Anyway, my antenna tuner I find is very noisy. It uses two rotar inductors and one is worse than the other. I ordered a can of Gold DeoxIT from eBay and hope to get it tomorrow. Will report on how well it works in my situation. Maybe our resident Chemist (NE1S) can chime in? 73 – Mike

12129. BK QSO Party comments

Yahoo group: AWAGroup (2014 — 2016)
Date: 2015-12-17 19:01:14 UTC
From: Ron Barlow
Topic: 12129 Message: 12129

Hello all,Many thanks to all participants, the AWA, and last but not least, Scott, WA9WFA, for making possible the great fun that was the BK QSO party! I would like to loudly echo the words of others that have expressed a desire for having more of these events per year. The 50 week wait for the next BK event, is much too long to wait! For the first time in many years, I did not hear a single west coast station, on any of the 3 bands. In fact, I don't believe that I heard as many Midwestern stations, as per usual. Some of this may have been due to my part time operation, that may have insured my absence, at the optimum times? In any event, I heard many more stations than I could "work", due to my QRP 3 watt transmitters, and long, lossy antenna feed line. The receiver that I intended to use gave up the ghost just before the BK start time. I was able to use my hb single band, single signal receiver on 80m, so no problem there. However, I had to resort to the use of a "broad as barn door" BC-455 ARC 5 receiver, on 160m (with a 1 tube upconverter), as well as on the QRM blanketed 40m band. I observed that I was able to easily hear an AM short wave broadcast station plus and minus 35+ KHz from its carrier frequency, due to the wide bandwidth of the BC-455! Not a good recipe for dealing with the SSB and digital sigs that infest the crowded 40m band! I was able to re-erect my fallen 160m inverted vee, just in time to permit QSOs with my good friends, K4JYS and W2ICE/1, on all 3 bands. Many thanks to Paul for sticking with me, as I struggled with QRM (that broad receiver!) and strong QRN. My QRP signal was not strong enough to permit a QSO with KB0MM, the only other AWA station that I heard on 160m, at around the suggested 0400Z time. Was anyone else QRV during that time period? I keenly hope to hear many of you during the LC event, next month/year! 73 de Ron n4gjv

Ron - that was my feeling after weekend #1 but I saw most of them by the second weekend. Condx were truly awful, almost like a curtain here, from Montana east.

I often see condx like this on the low bands in Decemeber...nothing in the central states but good signals from the eastern seaboard. I think it's a classic single-hop F2 distance, with most of the USA (for me) being in the 'quiet' skip zone. It was the same on both weekends but moreso on weekend #2.

> Was anyone else QRV during that time period?

yes...I was (1804) as well as KK7UV in Montana...never heard anyone else.

Hi, Mike.

Well, I haven't really done any chemistry for at least 30 years. The B.S in chemistry got my foot in the door at Fairchild Semiconductor (the original company) as a process engineer, but after a few years of that (which didn't involve much chemistry in the 1st place) I moved into process integration, and finally device engineering.

That said, I haven't forgotten everything, but I looked at my bottle of DeOxit-5 and all it lists for ingredients are Deoxit D100L, Petroleum Naptha, and Hydrocarbon Propellant. Since neither of the latter two are going to do anything to metallic oxides, I'd have to guess the de-oxidizing (reducing) agent, if there really is one, is in the "D100L," whose formula is no doubt a trade secret.

Sorry I can't be more helpful.

12135. Exotic Tubes to use

Yahoo group: AWAGroup (2014 — 2016)
Date: 2015-12-18 00:29:23 UTC
From: dulmagedon@...
Topic: 12135 Message: 12135

Speaking of exotic tubes from the list My UV199 arrived today. It tested good for continuity although could still be a dud.
so I popped it in the Colpitts and hooked up the power. So far no joy and I have been rubbing on it. Perhaps I am Copitts-ually challenged. Looks nice. I will set it aside for now.

Yes I would also enjoy more events. don't even have to be contests. Just somewhere to operate the old stuff. Been working on the 1930s style stuff for the Linc Cundall deal. Had the 47 ECO going for a bit today.

You and others have mused about the same thing. I even got an email at work from Lou asking about it. I didn't hear as many Midwest stations as well. Conditions were terrible for the most part. I heard 4 or 5 MN stations that I ALWAYS work yet I couldn't work them this year. I struggled with N9HAL in WI on 80m as well. Didn't get him.

I know of two 1929'er that passed away including Russ W0CWU (MN) and Ron WA9QNN (WI). There are one or two Midwest participants who are just occasional 29'ers, so between the occasional guys not being there, the SK guys obviously not being there, and the guys I missed due to crappy propagation, I'm easily down 7 or 8 Midwesterners.

I will comment and say that on the 2nd weekend, 40 meters finally opened up to the East Coast later in the afternoon and I was hearing Lou booming in, worked a couple of East Coasters.

Brad AA1IP authored this and posts it on the Glowbugs list every Christmas. I thought you folks might get a kick out of it, if you haven't seen it already. The "grizzled old ham" is supposed to be Frank C. Jones W6ANF who was the main guy originally behind Radio magazine and The Radio Handbook , also sometimes referred to as the "west-coast handbook".

Enjoy!

I could hear the Midwest but couldn't get a reply.Was looking at my BK copy sheets the other day. Neil is there and two others (I am upstairs the sheets are downstairs in studio B.) I am not very competitive but I do really enjoy the BK. I find more and more I am operating CW by choice. Did connect with Larry using my No 19 on AM a week or so ago but probably now about 85% of my ops are CW.

I don't know Lou, he is Lou Bozada in Rosebud MO. I was chasing Niel at the time and when I heard his call stuck around to hear it the second time to be sure. Thought of you immediately.
The UV199 I bought is a dud. Heater lights but it wont draw current no matter what.
Just in case it is something I did stupid even with my efforts to test it in socket now someone else is running a Colpitts and it seemed to me they had trouble getting it going. If so What was the trick?

Hi Don,

Before you conclude the UV-199 tube is a dud, try hooking up a pair of 9V batteries, 1Kohm resistor (for current limiting) and a sensitive milliameter all in series and connected between the filament F- terminal (pin 4) and plate (pin 3), with the filament lit (3.0V, positive on pin 1 and negative on pin 4) and the grid (pin 2) also connected to pin 4. I'll take a known good one and put it on my curve tracer and let you know what to expect under these conditions. Off the top of my head I'd guess probably around a milliamp or so, because the tube manual says Ip = 4.5 mA with 90V on the plate and -4.5V on the grid.

Remember the old adage: amplifiers oscillate, and oscillators refuse to. Sometimes.

73,

This looks like a pretty recent photo, why don't you ask the owner? I got the info out of Eugene Rippen's book, 2nd edition and it shows a top view but very small. The two large knobs are for condensers and the tube is between the empty space between the first coil from the left and the other two. 73 - Mike

You could wire the UV-199 into a known working oscillator circuit, like your Hartley or TNT, for a test. But remember the UV-199 is a low-power device, and won't take much abuse. I think maximum plate voltage is 90V, so don't push it much beyond that, and until you get 'er oscillating, I'd be more comfortable around 45 volts. I think we are talking QRPp here. Definitely be careful not to exceed 3.0V on the filament.
>
> Sp pos 18v on Plate.meter 1 K resistor and other lead to filament pin
> 1 with a jumper to grid. Watch the meter. Yes my meter has a 2.5ma

Filament pin 4 is F+/B-, so tie both the grid and the series combination of B batteries/resistor/meter to pin 4. Only F- (-3.0V wrt pin 4) goes to pin 1 (but see below).
>
> I am assuming so correct me if I am wrong that I should see a change
> in current with grid hooked and not hooked up? Is that correct?
>
I wouldn't float the grid, it could be dangerous to the tube (but probably not at 18V with a 1Kohm current limiting resistor). A good test would be to observe the change in plate current when you switch the grid from the F+ pin (pin 4) to the F- pin (pin 1). You should see a lower plate current with the grid connected to F- (pin 1), as the grid will be more negative wrt (most of) the filament.

Yes I did try that and there was a difference. When I build anything now with a direct heated tube I build a resistive network and feed both Fs from the middle of it and bypass them also with caps so Rf is relatively uninhibited . However I followed your instructions as close as was possible. I also redid the circuit as a hartley which takes about a minute to change. It made no difference. I have built so many hartleys I have a hard time counting them Not all stand alone txs but i can build them wthno digrams from memory and they always work so when this one didnt want to go I am suspicious. I could fudge in a 01A fairly easily to make sure the circuit runs. However I got a gut feeling have a worn out tube. The colpitts aside , hartleys are my thing and I dont have any that didnt go so I suspect the tube. I have a bad 45 that act similar. I will check further perhaps tomorrow. my personal appraisal is the tue still responds although somewhat porly but it doesnt have enuf umph to make it go. I will check further. Seems to me only .055ma is not enough to run a radio on. donVE3LYX

Niel,
Here in NC, during the BK, I found 40m to be very trashy. ...esp during late afternoon into the evening. But there were times when parts of our BK section was fairly clear. I was getting QRM from SA/Cuba/Mex SSB stns plus the digital at the low end. Sometimes I could squeeze in down at the bottom end just above the digital QRM. With xtals, you may have to hope for good luck in choosing xtal freqs. If possible, you may want to try to have a fairly good choice of rocks. With our low BK power, the above condx can be tuff on the ears of the rcving stn. One advantage in the LC is that some of us can run a tad more power plus some of our rigs may not have some of the characteristic notes of our '29ers, some of which were hard to copy amongst the QRM. Something else you might consider is listen around at the general times you plan to operate and see what, if any clear spots might be consistently free of QRM. GL in your xtal choices and in the LC...73 de Bill K4JYS

Joe asked tonite about the UV199TX. Here it is awaiting a good tube. Just a standard Coplitts shunt fed self controlled osc.
Also when I took this photo I stayed to run my breadboard 6l6 Tx for a bit and its regen mate. I had reworked the regen today to remove some hand cap problems and am happy to say it was most successful. I can even copy SSB signals easily now.
Have to stay up till 3 AM to hear SAQ broadcast (8:00 UTC) Installed a VLF SDR in my notebook and made an antenna coupler per instructions provided. Here's hoping.

12168. UV199 TX

Yahoo group: AWAGroup (2014 — 2016)
Date: 2015-12-24 08:44:03 UTC
From: N3IBX
Topic: 12168 Message: 12168

Hello Don,
It was a real pleasure talking to you, Lou, and Jim on 75M SSB last night on the "MSN" (Maple Syrup Net).

I read your post about your UV199 TX. You mentioned that you are: "awaiting a tube" for it. Do you need a UV199 (short pin) or a
UX199 (long pin) tube with good emission for your transmitter? If that is what is keeping it from being on the air please let me know;
and send a email directly to me at: n3ibx@....

Beside it being "Christmas" and "Boxing Day" within the next few days, I know the "199 Tube Fairy" and could put in a good word for you!

Merry Christmas and a HNY to all

Mod-U-Lator,
Joe Cro N3IBX

Don, are you referring to saqrx.exe?

I've played with it, but haven't hooked an antenna to my soundcard since downloading it. At least 10 years ago, probably before this program existed, I had a program called Spectrogram, or something like that, which produced a frequency domain display of whatever signal you poked into your soundcard. If you hooked an antenna up, it was a visual VLF receiver. I had tried to receive SAQ on that; no joy.

I've thought about doing a timed video, or at least audio, recording of the SAQ frequency so I don't have to be awake at that ungodly hour. I haven't had time to investigate any video or audio recording programs that have a timer function, and I didn't realize SAQ was going to be active last night.

BTW, I still owe you some data on a good UV-199. Been extremely busy, but will try to get to it soon.

73,
-Larry/NE1S

SAQ VO94, Comes with the timed recorder. I was up then and there was definatley activity but there is a glich between what Apps my notebook has and what they require. I did make both an RF recording and a AF recording. He(Johan) said don't throw in the towel if you are not successful the first time. So I don't know yet. I should have used my laptop which is no longer on the internet. Ithas dual inputs distinct. This has only an earphone jack and apparently his program repurposes it for input. Seems wierd to me. I tried my Sig gen, My Eico but it has no output on any band now so I will have to revive my Stark or wind a coil for my GDO. There is another broadcast in Feb I believe. What really threw me was his last comment on his help section. "Make sure you know what you are doing " I don't! I haven't a clue on computers.. I built a coupler, a pair of 1n94a back to back parallel (Here that is for me a normal CW pre- Clipper circuit when I am working in Solid State.) and he said a resistor but didn't say what. Since current is low I figured probably not critical or he would have said so so I popped in a 2.2 K left over from my tube tests. You owe me nothing Larry. You guidance was as usual excellent and I am as sure as I can possible be this tube would test as my Ancestor would have said "KAPUT" oder "shrott". Don't worry. enjoy your holiday. Hope to catch you on 40M again with my now Hi Power No 19 set.
Merry Christmas to ALL and Good DX in New Year.

12172. 2015 BK log for NE1S

Yahoo group: AWAGroup (2014 — 2016)
Date: 2015-12-26 18:40:49 UTC
From: Larry Szendrei
Topic: 12172 Message: 12172

Scott and AWA Group list,

I have attached my log for the 2015 BK. 33 contacts total.

I was not very active the 2nd weekend as we had learned the previous Monday that our beloved cat Casper was terminally ill; his kidneys had failed, and most of my enthusiasm for the BK and a lot of other things disappeared for a while. We ended up having to put him to sleep the Thursday following the 2nd weekend.

73,
-Larry/NE1S

Don (and list);

I finally got to getting a family of curves for a good used '99. I used a UX-199, electrically identical to the UV-199, but easier for me to make connections to: I don't have a UV-199 socket that isn't already in a radio.

Horizontal scale is 5V/division, vertical scale is 0.1mA/division, the grid is stepped at -2V/step, with the top (leftmost) curve being Vg=0V. Although there are some artifacts due to capacitance in the setup, I'm seeing Ip=0.9mA at Vp=20V and Vg=0V, slightly less than 0.9mA at Vp=18V, where you took your data. Based on what you observed, I agree your tube is a dud. Did you use 3.0V on the filament, and did it even light up?

Hope this helps and 73,
-Larry/NE1S

Larry,

My condolences on the loss of Casper. It hurts to see them get sick or lose them. My furry family member turns 11 in less than two weeks.

Hopefully I will get my BK log typed up and submitted today during the snow storm. I have been busy, busy, busy since the BK. Just when I think things are going to slow down, everything jumps into hyper drive.

73,
Paul

Thanks, Paul. Casper lived just short of 8 years; the following Tuesday
would have been his 8th birthday. We were expecting him to live well
into his teens, but, of course, there is no guarantee that any
individual will exhibit close to the average life span. I certainly hope
your "furry family member" lives a long, healthy, happy life.

Our cat Scooter used to put money on the bed. Where depended who he was happy with. Sometimes it would be on my side if I had done something for him and sometime on Linda's. Usually dimes but once a quarter. We never ever saw him do it. It would just be there. Now he puts his Catnip fish on whoever's chair he is happy with but also we have never seen him do it. I thought I had it made at first (like the goose with the golden eggs) then realized it was change from my dresser or what may have fallen out of my pockets that I didn't see. Anyway they are a member of the family. Sometimes better behaved.
Meanwhile , back in the shack, I have dragged out my 1923 vibroplex and am doing practice everyday. Way back when I used code (by law) I used a Speedex key for my right hand and trained myself to send on the heathkit paddle keyer with the left. I am too now and have been away from code till recently for many years , decades even, so such antics are now beyond me however I can still run the paddles a bit with my right hand and hope by Linc C I am OK with them.
BTW heard "anyoneS" as Tim calls him and Tim HLR on the Heavy Night fest last night. Tim was iffy but Larry's PM rig was banging in here about 5X9. I was on the 80M ARC5 and listening on the BC454 but didn't have enough suds to jump in. Not that I didn't try. Big group. Lots of powerful rigs.

Great cat story, Don. Thanks for sharing it. Each one is unique, and
each does unique things.
When I was a freshman in high school we had a cat that would chase
ping-pong balls when they left the table. He'd bat it all around the
room until he got it in a corner, where he would pick up the ping-pong
ball in his mouth, bring it back to one of us, and drop it in our open hand.

Only 5x9? ;-)

Yep, I was running the homebrew PDM transmitter. Amperex 7527A finals
(2) series-plate modulated in the negative power supply lead with a
class D 833A triode modulator. I was in there from about 7 -8:30PM EST.
Tim was running his "Viking 1.5," which runs about 150W of carrier out.
Thanks for the report, Don.

Well, you are looking at the best place to get one. Do not see them at hamfests too often. Yep, if I want something really bad I do not bid till about the last few seconds, same as everyone else, HI. I hardly ever win a “rare” or “scarce” item if I place a decent bid early. There are guys that will bid 20 or more time in small increments till they outbid you. Then of course they lose to someone else the last second or so. 73 – Mike

I use Open Office for word processing, spreadsheets, and drawing. They call Open Office a "suite" of programs (think MIcrosoft Office, but in my opinion better, and, of course, free). Included is also a presentation program in the suite analogous to MS Powerpoint, but I haven't had to make a presentation since I retired 5.5 years ago :-) The drawing program in Open Office is pretty easy to use. I'm not familiar with Acad, so can't comment on whether you'll find the drawing program in Open Office suitable for your needs. For schematics, JSchem is probably better than a generic drawing program. I don't know that these programs work under Windows 10, but I'd be surprised if they didn't. (The most up-to-date Windows operating system I have experience with is XP.) The Macbook I'm using now is my main computer and I have another older Mac, an Ubuntu Linux, and XP box here which all get used from time to time. I have Open Office and JSchem on both Macs and the XP machine. In Linux, Open Office is called Libre Office or something like that, but it is basically the same thing from the same folks.

I have been working on a MAG LOOP Antenna for my low power rigs. Whether it is any good I should know soon. I don't know much about the history of these things or when they first appeared but most who use them seem to like them. With a little luck I will be testing this afternoon.
Enjoyed some "maple syrup" (N3IBX & VE3LYX aka the two Xs) last evening but a couple of the "pancakes" were missing. It will be a few months before I will have a free wed evening again.

Ted (aka "the QSO wrecking ball") K1QAR was using one of these and had a good signal on 75M and 160M here from the Boston area. He has a lot of experience with them. He mentioned the other day when we were talking about RF exposure limits, etc., that the near-field field strength from these antennas is a lot higher than "conventional" antennas, so for those of you how run power, make sure you don't "cook" yourself!

730 PM EST wednesdays. Lou is NC usually.he misssed last evening but Pete W1VZR whom you probably know was in there. The band went for a crap about 8 and signals when from 20 over to "waddie say?" almost instantly but I could hear Pete and Joe could hear him so we finished it off anyway.
Yes I was talking with the XYL at breakfast today about how some folks run Mag loops in their shack and how I don't think that is wise. I am even nervous about a attic install. I have an old cement base with a pole hole in the back yard about 10feet out from my shack window and enough coax already out there to hook it up so that is where it is going. Just waiting for the paint to dry. Tuning will be a pain so I will probably use it on my rock bound rig mostly.

Freq? That is up to NC Lou.
I have the Mag Loop running. Very touchy on the tune. I don't know what to think. I have it on my homebrew AM transceiver, a screen modded 6v6 and am tuned up on 7290kcs so I may try it off and on for a few days. I am not at this moment bubbling with enthusiasm. Is it workable? Yes. Is it wonderful. Probably not. At the moment I don't think it will see my pre 29 rigs. It is though very portable.

I found available a original Dynamotor PSU for my Mk11 No 19 WS and was able to make a reasonable deal. I wish to thank again for the heads up here on the original Kijiji ad that I bought the No 19 sets from. I have had a lot of fun , especially since implementing my mod which allows normal power out and takes it from a curiosity to a very useable radio. I make at least one QSO per day with it and am getting good reports from most. I love its WW2 style audio! Sounds to me like it should have in 1943 which is what I want. I have also done some CW work with it including a successful "pond hop" which was received on a No 52 W S making it period correct both sides of the ocean. Would like to try it on MCW but don't know if that is OK Regs wise and who would I talk to? I also have a BC454 I need a bottom plate for but it works and I use it with my ARC5 stuff. My replacement uv199 has passed USPS Chicago sorting so hopefully will find its way here in a couple of days. I am anxious to get the little rig going. Made two mag loops this week. I think I would rather have a 80M vertical. I have also been practicing with my Vibroplex bug , inspired by Paul's comments last BK. I am getting more comfortable with it everyday. I have been using it a bit on my 6l6 breadboard rig but mostly on a piezo buzzer. If I can stay cool I am ok with it and probably about 14wpm which is for me with in my comfort zone. (10 to 15) Been doing a lot of Cw ops lately. Last night I thought I heard Neil coming back to me but if it was he was in a gone in a minute. 80M band the last two days has been really weird. Propagation changes by the minute. Got the 211 Hartley (40M) and the 6l6 breadboard (80M)ready for the LC event.Got to get more rocks for the breadboard. or move a few that are low up to in band. Great hobby! Love that1938 superhet build BTW. A very good implementation of the original plan.

12211. MOPA thoughts

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-01-04 01:02:27 UTC
From: Eric NO3M
Topic: 12211 Message: 12211

Hello

In preparation for this year's BK Party (2016), I put together a 45 (Hartley) / 865 MOPA over the last several days, currently built for 160M. After going through some initial tests and tuneup, there are a few observations that I'm wondering if anyone can provide insight upon.

I've built various self-excited rigs for 630M and 160M (Hartleys, TPTG, TNT) and a few MOPA (809/811, etc.). My current mainstay homebrew vintage rigs are a pair of 89 / 802 / 811 MOPAs, one for 630M and the other for 160/80M with plugin coils:

http://no3m.net/vintage/630m-mopa/
http://no3m.net/2015/10/mopa-transmitter-in-stew-perry-tbdc-warmup/

They work very well, are stable and have a DC note (89 Clapp regulated screen voltage).

Some things peculiar with the 45 / 865 rig. When the 865 amp tank is tuned for resonance / best efficiency, the note has some prominent 60 Hz sidebands, the ones at +/- 120 Hz strongest. The best note seems to be achieved if the amp's tank is tuned above resonance, which of course, reduces efficiency, and the sidebands are reduced enough to sound nearly DC. Thoughts?

The oscillator power supply is well filtered, but not regulated, with the 45 running at about 20 mA @ 340 VDC. The 865 runs at 550VDC, about 22 mA when the tank is resonant, which also seems low considering I've read at least one source that around 30 mA at 550 V is possible. Amp tank undercoupled? I'm using a 4 inch airdux type coil for the amp's tank inductance, with a break in the windings for 60uH and 4.8 uH, plate inductance and output link respectively. The "coils" are only separated by one removed turn. The output link is tuned with a fixed transmit mica (1000pF) in parallel with a 900pF variable. I am also using parallel feed, with the output link near the grounded end of the plate coil.

Another observation is that the keydown drift (chirp) can be mitigated to almost nothing by adjusting the 865's grid bias voltage. Normal for the bias to have that effect? This also seems very dependent upon the amp's tank tuning, bias needs readjusted for chirp mitigation.

Any thoughts, insight, recommendations or pointers would be appreciated. I have a few 10Ys for an additional MOPA to cover 40/80 later.

73 Eric NO3M

In my notes for my 45/865 MOPA, I had copied down an item from Radio Handbook 23 that the output link should have a reactance of around 100 ohms. That would be 900pF and 9uH on your output link. That would increase your coupling and lower the impedance presented to the plate, and hopefully increase your plate current and output. Let’s see what the experts on here say…

If it were me based on what I have learned building osc circuits and PAs I would lighten the 45's load. Probably drop to somewhere around 250 volts and make sure the coupling to the next stage is no more then necessary to get the signal there. I don't know the particular circuit you have but if it is cap coupled I would try 100pfs to see what happens. It might be too light but will tell you if you are on the right track and you can raise it till you find your sweet spot or balance point. I would do the output different but forget that. For now I would try letting the osc be an oscillator and let the PA do the work (heavy lifting) and see of that goes the direction you want it to. You may have to give up some power to get the sound you want but Cest la vie. Anyway if I was in your shoes that is what I would try for the few minutes it would take. You may worry the 45 needs to drive hard to drive the PA however to me that defeats the advantage of the Mopa. Otherwise you could just build an 865 Hartley. (I have a 211 Hartley so I know the feeling) Hard to give up Power though, I understand that.

>make sure the coupling to the next stage is no more then necessary to get the signal there.

Assuming the PA stage is running Class C, or at least biased to cutoff, the 865 grid will need some hefty drive from the 45 oscillator. In my own rig I ran the 45 oscillator with 395v at 32mA. The 865 grid is biased to around -85v. I was seeing 70%+ efficiency from the 865 PA.

>defeats the advantage of the Mopa.

How does operating the PA stage in class C (deep bias and big drive) defeat it’s advantage? The advantages are isolating the oscillator from the antenna, and increasing efficiency. We’ll see around 45% efficiency from the self-excited oscillators (on 80m anyhow), but 70% efficiency for the PA stage in a MOPA (also 80m).

How does operating the PA stage in class C (deep bias and big drive) defeat it’s advantage? Well now you are kinda putting extra words in my mouth. I did not quite say exactly that. I do know that the advantage of an Mopa is the oscillator is as you put it "isolated." I know if I want a good stable VFO I need it lightly loaded at the osc proper and need to strive to minimize any changes in voltage and draw as much as possible as well as temp etc. If it is heavily loaded it is not well isolated, for instance, driving the PA hard. Anything one can do to further isolate the osc helps its stability including as used in other TXs a buffer tube. To that end I have found running osc tubes near max values can be among other things a hum source. And that doesn't only apply to our self excited deals. Also a heavily loaded osc tends to change freq on keying(chirp) if the osc is keyed and even if the load changes dramatically. However since you have a similar rig to his and have spent sometime flogging it and have no hum whatsoever I'll crawl back in my cave and go about my business.

As I said that is what I would try and this is the reason why. I stand by that in my own shack still.

Hi Eric,

I don't have a lot of experience with old-time MOPAs*, but here are a few thoughts.

If the tuning and loading of the PA is affecting the note, it's a good indication that the isolation of the antenna circuit from the oscillator isn't great, or that the PA requires neutralization. (Do you have a neutralizing circuit?) Many newer screen grid tubes have low enough Cgp so that neutralization isn't required on the lower bands if the layout isolates the gazinta from the gazouta well enough. But I don't know about the 865, or if you might have some undesired coupling between the 865 grid and plate circuits in your layout.

Sidebands at multiple harmonics of 60Hz is usually an indication of RF mixing with 60Hz energy in the power supply in these rigs.

As far as the 865 grid bias affecting the note goes: for a given amount of drive to the 865 grid, the more negative the fixed bias on the grid the less the oscillator will be loaded, because the "conduction angle" of the grid circuit will be reduced. So I would expect the note to improve, and the 865 RF output to go down, as the 865 grid is made more negative. (Is this what you observe?)

73,
-Larry/NE1S

*I hope to change that - one is on the to-do project list.

Eric,

If you have an oscilloscope I'd suggest that you look at the waveform of the oscillator output to see if the 60 Hz hum is occurring there. You might want to try it driving the amplifier but with the amp B+ off, so that the oscillator is loaded but the amp is not working to confuse things. Even a simple scope with a link directly coupled to the vertical deflection plates should give you a look at the oscillator signal. Also, since the only source of 60 Hz in the rig is the filament power and if the oscillator seems to be the source of the hum, try running the 45 filament from a DC supply.

Thanks for all the input and comments.

I was able to get the AC modulation under control by tapping the oscillator tank further towards the plate end. The plate current increases to about where Steve noted his 45 runs. Grid current dropped to about 4 mA. There is still some chirp, but the oscillator plate supply sags from 400 idle to 340 under load, likely the source. Similar transformer as in the old HRO doghouse supplies as far as ratings. Might put a bleeder across the B+ to try to reduce some of the sag.

The output coupling stills needs work. I tried several mechanical lashups but seem to be stuck at about 35-40% efficiency or thereabouts. 7-8W out with 20W input. In the process, the 865's tank inductance got "hacked" down to 57.9 uH vs. the original 60 uH. The difference in tank Q should be only around 0.5 (12.7 vs. 12.2).

Anyways, fired it up and had a quick QSO with N2AD and a nice ragchew with Bill, K4JYS. Bill commented that the keying was hard, but an earlier attempt to use a keying filter I use on my 30s MOPAs didn't work very well. After coming back to the shack, I hooked it up and now it seems to work alright.

12227. UV199 TX Project

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-01-06 13:45:17 UTC
From: dulmagedon@...
Topic: 12227 Message: 12227

I received the new UV199 tube from Mike's buddy . It is a very good tube and tested in my own test jig at slightly above stated specs which is nice. It is approx 12 times the values of the dud I have. So that part is good however it is not an easy tube to get to oscillate. I have tried several tricks including rebuilding the tx with my standard hartley circuit that works on 01As and 45s with ease but so far I can't get it to go into osc. Could be because it is a low current tube everything has to be just right ir to put it another way it has no fudge factor. Whatever I poke away at it for a bit each day trying different things. It could be I have also made some glaring mistake and can't see it at the moment. A mistake that is caused by the accumulation of birthdays aka senior moment. I have been looking for an actual UV199 or UX199 Transmitter schematic.. I have found several references to in word but no actual descriptions or schematics. If you know of one PSE post it.

Don,

If I were you and were having trouble, I'd first copy the "known good design" from the article that Lou posted, including tank circuit. I can't tell if the thing is 80M or 40M; with the 250 pF air-variable it may tune both bands(?). The '99 may not have enough gain to oscillate readily on the higher frequencies - and 40M may or may not be "over it's head." It was an early tube, designed and brought to market some years before the short-waves were in use.

You know Larry, I hadn't thought of that. The freq thing. I ll bet you hit it bang on. As you know there is a sound when an osc wants to go (in the monitoring rx)and I can hear it but it just wont take off and I have tried a lot of things. I will also look at the article. I am assuming it is in files. I have tried Colpitts, Hartley and different combos of C and L as well a different grid leak combos. I have measured voltage and current so I see them in my sleep. Everything says to me it should go. I know the tube is not the best design but figured it would work as I found a few references to others in the early 20s using it for their first TX however no schematics have I found. It is a bit embarrassing because I have a room full of good running HB osc-ers however I'll live. Tis the challlenge that makes it fun. I am tempted to go right to 160m however I don't have a real 160M antenna although I could use the tuner. Probably I will aim for the low end of 80M. First I have to get it going. Thanks for the idea. I will see where it leads.

FB, Don. Another thing we were discussing on the Maple Syrple net a few minutes ago - note the value of grid leak in the Windom UV-199 xmtr - 2 megohms! That's more like one would use for a grid leak in a regen receiver, but, the UV-199, being a PW tube, probably doesn't want much grid current; hence, the high value of resistor. Had you tried that value for the grid leak?

I had gotten as high as 1 meg and a 220pf. I see only one real difference in the circuit from what I have and can try it and the 2 meg-er easily. My plate block cap is only .0001 because that is what I have but I can do a lash up and make it all exact. The circuit is so close to what I have it is scarey. Mine was from 1927 radio news. I usually build from memory but when it wouldn't go dug out the old book and double checked. The coil is different. 8 turns at 4 inch diameter. with 250 pf variable. There is no reason why I can't duplicate this exactly at least to get it up and running. Thanks fellows.

Subject: Re: [AWA Group] Re: UV199 TX Project...CKT

I had gotten as high as 1 meg and a 220pf. I see only one real difference in the circuit from what I have and can try it and the 2 meg-er easily. My plate block cap is only .0001 because that is what I have but I can do a lash up and make it all exact. The circuit is so close to what I have it is scarey. Mine was from 1927 radio news. I usually build from memory but when it wouldn't go dug out the old book and double checked. The coil is different. 8 turns at 4 inch diameter. with 250 pf variable. There is no reason why I can't duplicate this exactly at least to get it up and running. Thanks fellows.

To put a fine point on W1MK; It was totally destroyed in the hurricane of Sept. 1936.

It is with heavy heart that I wish to sell my "Double-M 80-meter transmitter. Living in a retirement community with its antenna restrictions has pretty much killed off any pre-1929 efforts from W7OIL. I would like to see someone use it to it's fullest capabilities. Best DX with this rig was between Michigan and here in Vancouver, WA.

I am selling the transmitter, power supply and 2 #27 (227) tubes along with a reprint of the original article. Price is $130.00 plus whatever the actual shipping charges are. Photos attached. Detailed photos available.

yup but it was kinda hard to do. I want to hook the UV199 up to one of my good working hartleys. However , this afternoon I took the circuit from the 26 QST and built it. I didnt have a 2.meg but I did have a 1.8 meg and a 220pf cap for GRLK so that should be good. As it certainly wouldn't buck with values that close. I use a .001 for plate blocking as that is not a critical value. Anything pretty well that will flow RF will do the job. Otherwise I built it exact. I used a 150pf fixed cap in place of the Variable for testing as I am looking for RF and freq isnt important just for testing. . So far no joy. Making the UV199 to 201A adapter will tell me if I am whipping a dead horse. I have at least 4 I can try it on. It could be I just need a good feed of Sauerkraut and Wurst to get mein gehirn wieder klappen. These things have been easy for me to build. I dont normally even use schematics. To be stumped by this little guy ticks me off but I have to make sure it isnt as result of a senoir's brain freeze or something. (something stupid I did)

Ja Lou, naturlich.
I just wired in a 201A to the new circuit by piggybacking a 45 chassis socket. Works like a dream. It is actually a pretty good working circuit. Stable and nice note. With the UV 199 nothing RF wise. Checked voltages. 90 on Plate, 3.1 on heater. There is no real good reason why this thing wont run on the UV199. It works just excellent on the 201A. MMMMMMMM. You dont wanna know what I am wondering.

12250. A newbie's type 27 Hartley

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-01-08 00:34:16 UTC
From: mattgoff54@...
Topic: 12250 Message: 12250

Hey guys, Im new to the group and to building these wonderful glowing devices so I would appreciate any help I can get. I put this Hartley together finally and have a bit of a drift problem. I dont know if this is considered normal but even after warm-up the frequency will drift in the following manner: while sending v's etc for 1 minute at 100v B+ the xmitter drifts upward about 200 hertz. At 200v it only takes 15 seconds to drift 500 hertz. Power supply is a Heath SP regulated and Im not getting a chirp, it just wants to drift away. The tube draws about 22mA at 200v, and antenna coil adjustment has no effect on the drift, the oscillator does so loaded or not. Changing the coil tap position also is ineffective. Caps and such include a 600pfd blocking, 250pfd grid with 8k "dogbone" for a leak, and 1000pfd across the key. Choke is one of those standard little three section varieties (I think 2.5mh). All wiring is 18 awg. Ive used 4 different 27's including an ST version, and have the same result. My initial thought was the tube heating during keydown and changing capacitance, but Im not pushing it hard at all so I dont know. Any words of wisdom are appreciated, thanks. Trying to figure out how to attach a picture. Thanks, - Matt

Be suspicious of everything in your grid leak. Heavy enough wattage wise and cap is stable. If I am suspicious I sub one to see if it acts different. Also make sure tube is not heating your coil and measure to see if you filament voltage is stable and sufficient. Never had a 27 but 45s I have noticed will get stupid if heater voltage is not quite there. It is almost as if the tube losses heat on transmit. These are things I have noticed on some of mine. The TNT being the worst.

Hey guys, Im new to the group and to building these wonderful glowing devices so I would appreciate any help I can get. I put this Hartley together finally and have a bit of a drift problem. I dont know if this is considered normal but even after warm-up the frequency will drift in the following manner: while sending v's etc for 1 minute at 100v B+ the xmitter drifts upward about 200 hertz. At 200v it only takes 15 seconds to drift 500 hertz. Power supply is a Heath SP regulated and Im not getting a chirp, it just wants to drift away. The tube draws about 22mA at 200v, and antenna coil adjustment has no effect on the drift, the oscillator does so loaded or not. Changing the coil tap position also is ineffective. Caps and such include a 600pfd blocking, 250pfd grid with 8k "dogbone" for a leak, and 1000pfd across the key. Choke is one of those standard little three section

varieties (I think 2.5mh). All wiring is 18 awg. Ive used 4 different 27's including an ST version, and have the same result. My initial thought was the tube heating during keydown and changing capacitance, but Im not pushing it hard at all so I dont know. Any words of wisdom are appreciated, thanks. Trying to figure out how to attach a picture.
Thanks, - Matt

I think I just found the problem. I forgot to mention that across the variable I put a 250pfd to get down to the bottom of the 80m. This put the variable maybe a little less than half meshed. Took the cap off and at full mesh im at 3.854 but dead steady.

Hi Matt, I think we passed an email message the other day regarding a 1929 Hull Hartley….

I have the Heathkit SP-17 HV regulated supply as well and it’s a fabulous 1929 power supply. What frequency are you running your 27 Hartley at?

The 200 V at 22 mA might be running the 27 a bit hard. The 100 volts might be a bit low. Can you just unload or remove the antenna link coil and get a stable signal? My Colpitts is rock solid on 160 and 80m but has had some drift problems in the past on 40m. I’ve backed off the HV and current like you did, and it still did it. I’ve felt that perhaps it is due to one or more of the fixed transmitting capacitors leaking or breaking down, or just plain heating up with those larger circulating currents. It’s possible the fixed LC cap isn’t rated to handle those currents or is just heating up. What type of cap are you using across the coil? 73, Scott WA9WFA

Hi Matt,

Although you've checked it with various antenna coupling, are you getting 'enough' coupling? Light coupling will raise grid current which can heat the grid structure in the tube. Checking your grid current and plate efficiency would be good indicators.

Other sources of drift:

>Too-thin capacitor plates, especially brass, will deform slightly when heated.

>Dirty and/or loose mechanical connections.

>Tube socket (thin springy pin contacts?)

>Capacitors.

Hi Scott, I think that must have been a different Matt...I dont see anything in my email traffic. Anyway the cap is an old square "Solar" bakelite. Its smaller than the usual two holed CDs and Sangamos, almost half the size so you might be right, it just may not be up to the task. Ill sub it out and see if I can get down to CW territory with a steady signal.

Ive been reading just about everything I can get my hands on including a lot of 20's QST from eBay (sorry if anyone here bids or has bid against me) and I really like to try and keep my efforts as close to original as possible. But yes the PS has been invaluable and sure beats multiple lashed up 5U4 jobs.

Thanks for the advice I'll keep tinkering.

Steve, didnt even think of the variables plates being the cause as mine are indeed brass...but after taking that parallel cap out its steady so I dont think thats the case. As far as coupling...I assume Im getting enough. The grid/plate coil is 12 turns and the ant coil is 5, typical 1/4 copper mounted to swing in right up against or away from the plate end.

Ja Lou, naturlich.
I just wired in a 201A to the new circuit by piggybacking a 45 chassis socket. Works like a dream. It is actually a pretty good working circuit. Stable and nice note. With the UV 199 nothing RF wise. Checked voltages. 90 on Plate, 3.1 on heater. There is no real good reason why this thing wont run on the UV199. It works just excellent on the 201A. MMMMMMMM. You dont wanna know what I am wondering.

Hi Matt, You must be a different Matt. I have a 29 transmitter up on Ebay and 'Matt' was asking me some questions about the power supply and keying of the Hull Hartley. Sounds like you zero'd in on your problem, leaky or heat of the fixed capacitor. In the past I've taken my nice big vintage fixed transmitting caps and put them on the power supply and run them up to voltage, hoping to either discover excessive leakage, heating, dielectric breakdown, or confirm they are good. I can't confirm if that worked but the old Colpitts wasn't jumpy at all this year. Stretch or compress the copper tube coil a bit to change frequency, or you may have to add a turn to bring it down a bit… I know, easier said than done with 1/4" copper tubing. hi hi

On the Heathkit regulated supply, I am always mindful to not get smug about the quality of my 29 transmitter signal. The real 29 guys back in 1929 didn't have a regulated supply, and they sure didn't have signal generators or oscilloscopes to check signal quality :) Between their crappy unregulated power supply, and possibly just rectified AC with no filter capacitors, then add in a 2 or 3 tube regen, it's amazing those guys worked anyone at all! I have a large collection of no-prefix QSL cards from the 20's and they are a real treat to sit and read about the stations being used. Guys running raw AC on the plate of some poor ole tube :)

73, Scott WA9WFA

I just saw this now. This seems way too high. That means the 199 is dissipating slightly over a watt and not oscillating. The tube might be gassy. Lowering the voltage and seeing what happens in my opinion is still a good idea. 73 – Mike

Scott, yes Id say that was it. I swapped it out for a few kv CD cap and it seems to be running steady. I guess I could change the coil and might, we'll see.

My intent is to use the heath power supply to get the rig going before I throw in the homebrew PS variable. I have an 80 and an old Thordarson, while not 20s vintage, that I think might work well but at 300v not for a 27. A 210 is in the mail however.

I have a lot of respect for the early amatuers and what they were able to accomplish with that equipment. Ive always loved early tube gear, got my first Atwater Kent I think when I was 14 and thats when I started trying to build a TNT like I saw in my "official 1934 shortwave manual." It didnt work so well. It didnt work at all.

Hi Matt, I'm glad that you found a cure for the problem! I have not found success, with the use of any solid dielectric capacitors, in the several "power" oscillator type transmitters, that I have constructed (using the type 27, 10, 841, and triode connected 24As). The relatively large value of circulating RF current, the occurs in such power oscillators, seems to be of a magnitude that causes heating, and thus, a change in the capacitance value, of any solid dielectric caps, that I have on hand. I have even attempted to use multiple silvered mica caps in parallel, for the "fixed" portion of the LC tank circuit, which effected an improvement, in the drift rate, but the drift was still present. The substitution of an air dielectric padder cap, in lieu of the solid dielectric cap, effected an immediate cure, for the drift
problem. 73 & GL de ron n4gjv

I forgot to push the" . "! But forget it all. I dragged out my best meter for measuring MA, put it on the 10ma scale and I put on my new glasses which is no small thing. So I tried your suggestion Mike. At 45 volts 1.4MA and 90 volts 2.4 ma. Yes I was "guessing" on the wrong scale without my glasses. I should know better.
Anyway moving right along. Specs call for 2.5ma at 90 volts so that is I would say acceptable. 1.4ma at 45 seems reasonable to me. I would say the tube is OK. I suspect it is no good for RF or needs a lot of feedback, more then it is getting in the circuits I have tried. I would think the tube lacks natural internal capacity compared to others we use. An Armstrong circuit might do because it is easy to make it with excessive feedback however to my way of thinking, as cute as it is, this is not a good tube for a power oscillator. And I suspect is not, as Larry suggested, perhaps a wonderful tube for HF. It might go lower down in freq. I m going to rest here for now. It is an oddball tube being the only one with a 4E pinout. So I asked myself, "Self , why are you building this? Do you need another TX? No! Because I had the socket and didn't want to waste it. Is that rational? Probably not!" I don't think this circuit is going to oscillate. I don't think the tube is up to it. That said I do like the new circuit as it sounds really good on the monitor RX when I have the 201A in it. So I have decided for now I will build a proper UV 199 to 201A adapter and run it with the 201A. Anytime I come across a UV199 I will try it. Maybe someday I will find one that will run. I will be most surprised if I do. How do I justify the QST story? I can't. I am on 80M with it now and I might try it at 160m just to see but I for now am reasonably satisfied that is how it is. If anyone is convinced otherwise dig your tube out and make one. It doesn't take long to do. I would be interested to see the results.

So I have decided for now I will build a proper UV 199 to 201A adapter and run it with the 201A. Anytime I come across a UV199 I will try it. Maybe someday I will find one that will run. I will be most surprised if I do. How do I justify the QST story? I can't. I am on 80M with it now and I might try it at 160m just to see but I for now am reasonably satisfied that is how it is. If anyone is convinced otherwise dig your tube out and make one. It doesn't take long to do. I would be interested to see the results.

Here is the one I built yesterday afternoon. The small piece beside it is an adapter I made today to run a 201A etc in the UV199 socket. I built the rig from the 1926 QST article as close as I possibly could.

Don –

That grid leak looks like it is 470K, which may be good enough. I would also prefer to see a mica across the grid leak and not a ceramic. 73 – Mike

Hi Lou, I’m just continuing to downsize. Over the past 8 some years I’ve sold off over 85% of my stuff and in a couple of months I’ll hit 90%. I’m very close now. I did have an outrageous amount of radios back then.

I have four 1929 transmitters in various states. This Hull Hartley, my original 80 M 2x27 MOPA, my current 40m/80m/160m push pull Colpitts, and a 40 meter Colpitts LC given to me by John Rollins in thanks for handling the 29 QSO Party for him. John’s LC tank circuit is gorgeous as John was a master builder. I want to finish off Johns 40m Colpitts this year with a 211 tube just like the one Tim W1GIG has, and then use my other Colpitts for 160 and 80. So I’m moving the Hull Hartley on.

I’ve got some other 1920’s early 1930’s equipment that I’ll be selling off. For example I have an original early 1930’s station that was some OT’s station back then. It’s a crystal controlled transmitter and what I believe is the “Rationalized Autodyne” receiver. I have another Rationalized Autodyne receiver, and a mid 1930’s home-brew superhetrodyne receiver made with the round National IF transformers like those found in the FB-7. I also have a 3’ wide early 1930s multi stage transmitter that has one of those cool globe looking 860’s. I have no idea how to ship the transmitter as a custom box will be needed. Also will be selling a National built Lafayette SW-5 like receiver. Then I’ll be selling my super rare National SW-3 Model III which was the last SW-3 model made, with the headphone jack and B+ switch on the front, the antenna and ground terminals moved to the left side, octal tubes, and pin jacks on the right rear for headphones. I also have the original doghouse supply and the original 3 sets of Model III specific band spread coils for 20,40,80m, and the coil boxes. I casually looked for 25 years to find that receiver and only know of one or two others. The Model III was said to be built up into the early 40’s.

It was so much fun to acquire all the old radios but such as pain in the butt to advertise, pictures, box and ship :)

Hi Don, That 2.5 ma @ 90 plate volts, is specified at a grid bias of -4.5 volts. I suspect that you are using grid leak bias only, in your Hartley oscillator. If that is true, the tube will be operating at zero bias in a non-oscillating state, and the tube should be drawing much more than 2.4 ma., under those conditions. I suspect and fear that your 199 is suffering from low emission (and thus, low transconductance)
problems. GL& 73 de

Ok Ron, That would make sense. So I will keep it as a UV199 in the hopes that someday I get a real good one. I remember way back when I first ran the 45 TNT I only had one old 45 and it was pretty well pooped. If I wanted it to oscillate I had to push the heater voltage to almost 5. I figured it was low on emssion as well. I know guys terrible thing but I had zip to lose as it was no good otherwise. I got away with it for a quite awhile until the day Lou and I had a sked and on warm up it popped and I had to toss in a 201A for the Sked. Lou raided his supply and sent me a 45 which is still working real good on .2.5. and I take real good care of it. This tube the UV199 acts the same way. But since it is so rare and I have only one that is any good at all I am afeared to do that to it. And having bought 3 tubes already I have spent my wad for now. However today started of well. I rose early and checked into the Old Military Radio Net at the 6 AM check in. Next in line to me in the order was ANOTHER! No 19 set. N3XON I beleive was his call. We heard each otheralthough not great in fact I handed off to him. Always wanted a No 19 to No 19 contact so now I have that done. BTW Larry . Tim HLR was in there on his ART13. Strong here. Good group they are but start at 5 AM. I am dangerous that time of day but now I can at least reach them and check in.I also want to work Joe with his Angry 9 someday and he also has a No 19. Anyway I plan to put the new rig on freq and put some cables on it for the PSU and key. If all goes well I will be torturing Lou by evening. Last night I had the 6l6 breadboard on for awhile It is doing a good job for me. Been thinking about making a 211 Crystal controlled rig as I still have one Big Socket left and love that tube.

Don,

I have been watching this thread with great interest...

Seems that many battery radios from the 20's used the '99 as a regenerative detector. Some home-brews using a pancake (spier-web) coil would get up to 40 meters. Yes, oscillating so that CW could be received. IMHO I think the external circuity constants are "off" and that you already know how to build a regenerative radio, simply work from that point of view. You have proven that it will not work as a direct plug in, into the existing circuit. Wish I had the time to tinker, I have all the stuff and the Ham ticket, CW sucks though.

You may have "roasted" the '99. They have a thoriated tungsten filament and can be rejeuvenated. There are sevral proceses, each thakes a more severe approach at restoring emission.. The first one is simple. Discommect the plate and the grid from EVERYTHING. apply 4 volts to the filament for an 1/2 hour. If no joy I tell you the rest of the steps right up to the one where you put 7.5 volts on the filament Yeow!...

The layer of active thorium is only one atom thick, too much plate current will pull of that layer into oblivion, actually I think it gets stuck to the plate. BUT there is more thorium in the filament wire all mixed in... The trick is to get the filament hot enough, depending how far in the thorium is after hours of use, and bring it to the surface. This process will not work forever. At some point all the thorium is used up. Evidence of that is the tube will have no emission even after the brutal flash and cook cycle.

If your 99 shows gassy, save it for the receiver a gassy detector has a non-linear curve that is great for sensitive detection...

So don't give up just yet...

Chas

Not quite. The 30 has about twice the amplification factor, and transconductance, as the '99. Should be able to run at a couple of watts DC input, and a '99 won't do that. Maximum plate voltage is 90 for a '99, and double that for the 30. The 30 should be much easier to coax into oscillation.

In my grandfather's broadcast band regen using a UV-199, I had to put a 10pF capacitor between grid and plate to get it to go into oscillation at the low end of the band.

For BK purposes, the 30 wasn't available in 1929.

Well as you know Tim doesn't give Q5s away. He is well over 3oo miles from me so I am happy. The closer ones including Ted NC had the most trouble. He is quite a bit closer then Tim to me. In fact I just looked that up now. Also there was an SSB guy spilling over real close which certainly doesn't help anyone. I had trouble copying Gary 100% ONLY for that reason. Had it been clear it would have been no trouble as his signal was reasonable. Anyway just as an interest I was never able to check in with my ARC5s or Dx60B barefoot so I am pleased to put it mildly. It is my third check in with the No 19 so it is doing the job for me. I told them I was only in for one go-round (as the XYL was waiting for me to take her out for breakfast) but it was nice they gave me a second shot even if I wasn't there. I know Tim is running a ART13 but other then Gary's other 19 I don't know my US radios well enough to know what they are running for power. I could pop the Amp on but seems cheating to me. However for the DX60 net I set it all up so I can be well heard. But it is a different deal. Sorry I missed you. Tis an early net. I want to hear an Angry 9. Joe has one and we may try it someday between us.
Well I am glad you guys started it Mike. I have listened for quite awhile (maybe over a year) but tis nice now to be able to check in. I try not to use un others time at the mic. Just glad to be there and here those wonderful old rigs. I am really enjoying the No 19 now. I use it everyday.
The point about the UV199 as a regen is well taken. The thought had crossed my mind that as I said before it might go as an Armstrong. Anyway I was working on proper power wiring this morning but have to work on the 63 Dodge today as I borrowed a brake drum puller for today so I can service a rear axle seal. We will see how things go.
My GDO has developed a break in its heads cabling which is very annoying. Gets in the way of development. Anyway I tried it on 4 volts just to see. No joy. I will poke away at it and if it is possible eventually I will get it going . It would be nice to have an actual build specific for the UV199. It is mentioned in the26 QST article as one of the tubes but I am beginning to wonder . That rig was built for a 201. I have copied it as close as possible and I have built a lot of osc and regens so when it wont go I wonder. My values are so close , closer then tolerences would be so it should be singing. And when it runs on the 201 well makes one wonder. I wrote tech stuff for magazines for over 20years so I know some of the things that happen when success and deadlines cross purposes. Not always the writer who makes the jump. Sometimes words are put in you didn't write or say.

12294. Transformer question -

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-01-09 21:32:13 UTC
From: Mike Feher
Topic: 12294 Message: 12294

Sometimes it seems the more I know the more evident it becomes to me that I know less than I think. I recently obtained an HF solid state amp that runs off of 24 volts at about 80 amps peak. I do have a PS for it, but, the PS runs off of 220. I see some reasonably priced transformers that convert 220 0r 440 at about 2 KVA to 115. The question is, how efficient would these be to run backwards? I believe in most transformers the primary is the inner winding, which helps to magnetize the core more effectively. Simple thinking would make me think there would be no problem running these in reverse. Any good reasons any one can think of why that may not be a good solution? I moved my ham shack into one of the upstairs bedrooms and I only have 120 there. Thanks & 73 - Mike

Hi Mike. Funny that you ask this. I had a similar question back when I was building a PS for my amplifier. Here's what I have in my notes after asking some amp gurus..

If you stay within the VA ratings for the windings it may work fine. However, you might consider the inrush current rating on the primary side (which you will be using as a secondary, and vice-versa). The secondary-cum-primary may have to be derated by some amount to stay within current and heating specs. The relative power coupling of the two windings will also change, requiring further derating.

With 24v at 80A (1920VA) load. That doesn't leave much room for derating from 2kva.

BTW, I ended up finding a suitable HV transformer and not having to run one backwards. I also bit the bullet and brought 240v to my shack.

Whew, my younger brother was here for a visit so I got diddly done this afternoon so that cuts me some slack Lou. I give you a heads up when it is ready for a QSO.
Re 30 tube. The trouble there is a 30 goes where a UX199 goes, not a UV199. It looks like a better candidate for a tx then the 99s Anyway I am going to coast for awhile and think it through. All this work for, if I am lucky, .220ma input. Not sure this makes sense anymore.
Heard from the other No 19 guy this afternoon. He runs a Series Two Mk111 Amp (very rare piece)on his and uses the Intercom to modulate it. They made a control box to do this here in Canada and it is simply a plug in deal. I used to know the number of that box but have forgotten it now. His rig sounded good and he said the same as I just said earlier.
"Without the SSB interference we both would have been just fine."
We are going to try a 40M contact some day soon.

Subject: RE: [AWA Group] Transformer question -

Hi Mike. Funny that you ask this. I had a similar question back when I was building a PS for my amplifier. Here's what I have in my notes after asking some amp gurus..

If you stay within the VA ratings for the windings it may work fine. However, you might consider the inrush current rating on the primary side (which you will be using as a secondary, and vice-versa). The secondary-cum-primary may have to be derated by some amount to stay within current and heating specs. The relative power coupling of the two windings will also change, requiring further derating.

With 24v at 80A (1920VA) load. That doesn't leave much room for derating from 2kva.

BTW, I ended up finding a suitable HV transformer and not having to run one backwards. I also bit the bullet and brought 240v to my shack.

Sorry to jump right back in. I have the little rig all done, cabled with key jack installed and the 201A in the adapter installed. It is a very interesting rig because it has no chirp. Tube drifts a bit if you start up cold but even that is minor. Not enough to require twisting the RX dial at all. Just enough you know. Actually I just realized it is less then my Kenwood TS830S does so it is almost not relevant. At 245 volts key down it draws 13.4 ma. Not a lot so it isnt going to be supper powerful however if I was building a MOPA this is the MO circuit I would take a hard look at. The QST article said he was told it sounded like a Crystal controlled rig. It actually does. Power out ? Maybe a watt or just over. Not a lot. Will need good conditions for any distance but it is is a nice little rig. Tunes easily and stays where you put it. I have it right on 80M. Full mesh is bottom of band. (A fluke , cause it certainly wasn't planning.)

Thanks Larry. Yes, I often see his posts. I did also find a 3 KVA version of the same transformer, so, if I go that route then I'll probably get that. Now the biggest concern will be to make sure I have a dedicated circuit for it in that room and a large enough breaker. I do not expect to necessarily use it on high power all the time or continuous duty, but, it should be able to handle the peaks. Thanks & 73 - Mike

Hi Mike et all, FWIW, some examples of transformers that I have used, long term, in the "backward mode", include an ancient "pole pig" transformer that I used in a 2.2 KV HV power supply, and several "control transformers", that have been used as to source the high voltage, for lower power transmitters/power amps. These transformers have always run cool, but none of them were pushed to their limits, or used to supply loads that were of a 100% duty cycle nature (CW only transmitters). Note that the original primary winding, must handle a bit more power than the original secondary winding did, to compensate for transformer losses. When the roles of the windings are reversed, the "new" primary winding may be overloaded, if the chosen wire size was originally marginal for the task, and the transformer is pushed toward its max rating. You may not have a problem with the use of the 2 KVA transformer, for a low duty cycle application, but the revised plan to use a 3 KVA transformer would seem to be a good idea, for a high duty cycle application. Good insurance (and slightly better regulation) in any
event. 73 & GL de Ron n4gjv

Good afternoon all,
I know a lot of you use coax fed antennas for many of your BK and
1930s xmtrs. I do for one which I use on 160m. However, I am still
a tad perplexed and this has been bugging me for a while....just how
many turns do you generally use for the link coil to the coax line.
Does it make any difference? Also,when using the coil around the
tank coil, in the case of plug in coils, or at the end of the tank coil,
does it make any difference what imped. the antenna being fed is....ie,
coax, end fed, sgl wire fed windom, etc. Should a certain number of
link coil turns be used for a certain imped. antenna. Here again, does
it make any difference. Will 'the more turns the better' (within reason)
work here as far as power transfer to the antenna. Any clarification
would be much appreciated. Tnx....

>how many turns do you generally use for the link coil to the coax line. Does it make any difference?

About half the turns for my rigs and 50-ohm feed. My 160m coil is 12 turn link for a 20-turn tank coil. It made a difference if I strayed too far with the turn count, in that tuning Q and output efficiency were affected - - at least that seemed to be the case when experimenting with my MOPA and Hull Hartley. The antenna link circuit is a series LCR with R being the antenna load. Too much L in the link needs a lower load cap C to provide the proper plate loading and output peak, but does so with a higher tuning Q which made the loading adjustment touchy and critical. Any antenna movement and change in the load affected the frequency stability probably due to changes in the plate load. Conversely, too little L necessitated a higher load cap C and a low Q, which did not permit peak output and efficiency. (I always thought my note sounded full of harmonics with a low Q antenna link.)

>>does it make any difference what imped. the antenna being fed is....ie,coax, end fed, sgl wire fed windom, etc.

Yes. If your feeding a high impedance, you’re essentially trying to couple the high impedance plate load to a high impedance antenna load. The ‘optimum’ coupling turns will be different, or it may be like those pictures of the antenna wire clipped directly to the tank coil. In other cases the antenna coupling network may have to be a parallel LC lash-up. It would surely be beneficial to measure the impedance your feeding.

Ok, Lou, sorry. Anyway Eric was right there. Good signal. He caught me off guard. I was half expecting no contact but he is 212 mi from me ATCF so I guess it works better then I thought it might. He said I had some AC on the signal. I was running the tube on AC heater power because my battery powered PSU has cathode and heaters preconnected which prevents me from keying. Tomorrow I may simply rework that PSU so it can be keyed in the PSU and that will work on any of my 29 rigs. Was is really spooky is the lack of chirp. Anyway I appreciate Eric being there and coming back to me. I am home now and am going back on at 9PM anyway. Let me know when your free tomorrow if that works out and we can try one between us.
Paul I hope your power is back on. Larry was having house issues as well. I hope that is in hand.

40M 2 turns out, 80M 3 turns out. More is not better. It is easy to have too much. Especially on the big coils. I check with a lamp if I am in doubt. Makes quite a difference in usable power out. I use lamp cord for my vintage stuff. It is 75ohms more or less and works well. Otherwise I run a single wire feed. and ground the other end of the link. I am sure that is all nuts o some but it works very well. I don't think coax was available in the 1920s but that is just a guess. The new rig runs no link but is true to the 1926 schematic.

Don

Seeing just a slight upward chirp on your characters while listening to QSO with Paul, N1BUG using Fldigi waterfall. Maybe on the order of 10 Hz or so. QRN pretty rough tonight.

Yep - some water in the cellar, which happens whenever we get a large amount of rain in a relatively short period. It's a cellar, not a basement (and therefore totally "unfinished"), and I've got most everything elevated from the floor surface. I had to set up the portable floor pump and run it for several hours. Nothing left now but a puddle or two in the low spots. It's kind of a pain, but not much of an issue.

I couldn't quite hear you on the PM-AM net yesterday - too much noise here with cratic stashes, etc. Also had a problem with Bill W2DGB, although I was getting more from him.

On my PPTNT I feed the nominal 50-ohm system as follows:

160M: 1.5 turns from CT/B+ feedpoint
80M: 1 turn from CT/B+ feedpoint
40M: 1/2 turn from CT/B+ feedpoint

These were empirically determined to be the best compromise between best note and RF output.

I run a resonated link output on the Hartley, and the link is 4 turns on 80M, where it's been parked for years. I suspect more turns on the link may be better, but there's no more room on the shelf where it resides to add more.

Well, based on the inputs here, I purchased a 3 KVA transformer on eBay. I realize the inrush, magnetizing current, will be greater with this one, but, I will also have more overhead.

This is the one I bought:

http://www.ebay.com/itm/291062672952
<http://www.ebay.com/itm/291062672952?_trksid=p2055119.m1438.l2649&ssPageNam
e=STRK%3AMEBIDX%3AIT>

The seller accepted a $55 offer, so it is not too bad. It weighs 75 pounds, which is a lot, but does not seem that much for 3 KVA. Must be due to the new materials they use for the core these days. Thanks & 73 - Mike

Any thoughts on which end of the coil to couple the antenna to? See https://www.prismnet.com/~nielw/tnt/tnt.htm . This Nov 1930 QST George Grammer design has the antenna coupled to the RF hot/plate ends of the coil, not the center/B+ feedpoint.

The classic Hull Ross Hartley (http://w0vlz.blogspot.com/2009/09/1928-hartley.html) also has the antenna coil on the plate end of the tank coil.

I believe, though, that somewhere I saw a regen receiver recommendation to couple to the ground end of the tuned circuit/coil in order to minimize capacitive coupling to the antenna.

Does one end or the other make the transmitter more or less sensitive to the antenna sway?

Comments/experience?

For link coupling, it is considered best engineering practice to couple to the RF-cold side of the tank coil, because, as you've said, it minimizes capacitive coupling, which can pass harmonics to the antenna.

As far as feeding directly from the tank coil goes, it depends on the impedance the antenna system presents at the transmitter: for low impedance systems, the best match will be close to the RF-cold end of the tank, and higher impedance systems will want to be fed closer to the plate end.

Larry,

For feeding directly from the B+ hot tank coil to a 50 ohm / current fed antenna what size/type of blocking cap is used/recommended?

Well I am glad you had no big trouble with it. re AWA net , I could hear you not bad , Tim just barely, but readable. JIX was tough as was one other (maybe the fellow between us on the list.) I was trimming the wick down where you and Tim were as well so knew you would be in. Today after a long search and a long wait I got an original PSU for my MkII No 19. It looks pretty decent considering its 73 years old. I have the power cables and a 12 volt back up system in the shack so I will be fine in no power situations. I never expected to find a working one. Price was fair and Greyhound did the shipping. I will check it over before hooking it up. I see one minor thing that needs attention already.
Lou,
3539kc at 4 pm? Will that work for you?

For feeding a low-Z like 50 ohms, of course you want a low reactance at the lowest frequency of operation. I used a .02uF 2500V mica on my TNT, since I use it (occasionally) on 160M. At 1.8 MHz that's 4.4 ohms, which is an order of magnitude below 50 ohms, and that makes me feel warm and fuzzy :-)

As far as voltage rating goes, I'd use a minimum of 2X the DC plate voltage and higher if possible.

From: Ron Barlow
Topic: 12309 Message: 12333

Hi Bill et all, I use a 2 turn on 40m, and a 3 turn link on both 80m & 160m, to couple my Hartley oscillators to a ~ 50 ohm load. A 4 turn link would probably be desirable on 160m, but physical constraints prevented me from using the same set up that I used on 40m & 80m. My alternative method required that I wind the link partially over the cold end of the tank coil, resulting in tighter coupling. As a result, a 3 turn link proved to be adequate. When using an untuned link, as I am doing, the amount of coupling between the transmitter, and the load, is affected by the number of turns, on the link, and by the spacing between the tank coil, and the link. More turns equals tighter coupling, and conversely, fewer turns equals looser coupling. Less spacing between the 2 coils yields tighter coupling, and a greater spacing yields looser coupling. The power transfer will be maximum when a particular discrete amount of coupling is provided. The power transfer/output will diminish, when the coupling is either decreased or increased from the optimum amount. Thus, it is desirable to provide a means of conveniently varying the coupling. FWIW, the following statements describe my chosen method of adjusting my transmitter output coupling. The only piece of test equipment that is required, is a small pilot Iamp. First of all, I provide a dummy load that consists of, or (preferably) includes a pilot lamp or lamps.For example, a suitable load for a transmitter that is expected to deliver an RF output of ~ 1 watt could utilize a # 47 pilot lamp (rated at 6.3 volts @ 150 ma, thus its hot resistance is ~ 42 ohms). A 10 ohm, non inductive resistor is added, in series, to yield a ~ 50 ohm termination, that includes a visual indicator. Note that the lamps should be used at the ~ full brilliance level, as their resistance varies substantially with brilliance changes. The "normal" 42 ohm resistance, of a # 47, will be substantially lower, at a reduced brilliance level. Next, construct a link that consists of the # of turns that is mentioned above, while including some means of adjusting the spacing between the cold end of the tank coil, and the link. To facilitate the adjustment, I fasten the link, which is composed of #12 AWG insulated solid copper wire, to the transmitter baseboard, and I adjust the mean spacing distance by bending the leads, at the link base, to either tilt the link toward the tank coil, or away from it. Apply power to the transmitter, and adjust its frequency to approximately that which will be ultimately used.Adjust the link to tan coil spacing for max lamp glow. If the brightness peaks at a link to tank coil spacing of 1/2 inch or so, with a drop off of brilliance at greater or lesser spacing, simply park the link at the max brightness spacing, and you are "good to go". If the brightness peaks at zero spacing, add another turn to the link, and repeat the test. If, on the other hand, the output peaks at a wide spacing (say > 1.5 inch, or so), you may wish to reduce the size of the link by a turn, or a fraction of a turn, before repeating the test. Next, note the plate current, before disconnecting the dummy load. Finally, connect the antenna, and after re-checking the frequency, observe the plate current. If the VSWR on your antenna is near unity, the plate current will be unchanged from that noted, with a dummy load connected. If it has changed by < 25%, you may wish to tweak the coupling adjustment, to bring the plate current back to that level observed, with a dummy load in place (or reduce the VSWR on the antenna system). If the plate current level changes > 25%, something is awry!!

As for the use of an antenna system that has a higher Z, such as the single wire fed Windom, I suggest he use of a larger (more turns) link, which should be tuned to (parallel) resonance, with a variable cap. IMO, the use of an untuned link, of adequate

size, would introduce a undesirable amount of inductive reactance, into the system. I hope that this is useful. 73 & GL de Ron n4gjv

Now that I have a few QSOs under my belt with te last 1926 QST Hartley rig I am tuning my attention to the Linc Cundall Event. I am a just for fun participant so coring is not a big deal to me. However I would like to run the Big 211 Hartley (AKA Big Bertha) for a few contacts. I don't have a 40M receiver other then my No 19s receiver so I wont have a good score to offer for RX year. Power is 44 watts input which is also not wonderful I guess but I would like to get a few with it if I can. It has a big raspy sound. It is a 40M only rig and I normally run it around 7040 or so although can tune the whole band if I want to. My intention is to run it Wed night and a bit on Thursday. The rest of the time I think I will put my No 19 in CW mode and run it for most. I may fire up the ARC5 and the BC454 . All my military rigs are 1943 production. If I get tired I may fire up the breadboard station which is also 1943 (built from the 1943 handbook.). It is rockbound on 80M with a regen receiver. I am looking forward to both days. Hope to here some of you there.

If you have access to the QST archives, there is an article on pg 29-31 of October 1959 that discusses three output networks, series resonant, parallel resonant, and untuned. Most of the article is calculation to arrive at practical circuits, but measurement methods with GDO noted.

On the 29 MOPA I am working on, after frustration with a link coupled output, I tried capacitive coupling using an old Aerovox transmit mica (0.05uF). Tap adjusted for max output into a 50 ohm resonant load, ending up a couple turns or so above the "RF grounded" part of the coil. This type of lashup is nothing more than an autotransformer. If you have a single-ended split tank (ie. RF grounded tap in the middle or thereabouts, whether using series or parallel feed), tap output to capacitor between "ground" and plate end, on double-ended (PP) tank, two capacitors and associated taps out from "ground" feeding a balanced output.

I was touring your site (always very interesting) and checked to see if you are on air. You were not but I see you have been operating 3542.7kcs for a bit this morning. I have been hitting the same reverse beacon with my 1943 6l6 breadboard. I am rock bound so have limited mobility but am running a 3542 rock and showing 3542.1 to 3542.2. Since I see from your report you can hit down here and further east I am going to see if I can work you during LC with the 1943 station. I heard you once the other day but QSB wiped you out about a minute later. However when I could hear you it was strong and clear.
I am also rather nervously interested in trying a QSO using my Vibroplex bug. I know I will mess up but if some patient soul would want to give it a shot I would be willing to embarrass myself trying.

You can also feed an unbalanced system from a double-ended (PP) tank coil, by simply tapping up from the center/B+ feed point on one side - yes, it will upset the balance a bit, but not as much as you might think. Usually the balance isn't perfect anyway, and you'll get better results on one side of the coil vs. the other. This is the method I use on my PP TNT to feed a 50 ohm unbalanced (coax-fed) system.

12339. AWA Linc Cundall Memorial CW Contest... Tomorrow!

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-01-12 17:21:13 UTC
From: Louis Vermond
Topic: 12339 Message: 12339

AWA Linc Cundall Memorial CW Contest
?
?Dates: Wednesday, January 13, 2016 @ 2300 GMT to Thursday, January, 14, 2016 @ 2300 GMT
And
Saturday, January 16, 2016 @ 2300 GMT to Sunday, January 17, 2016 @ 2300 GMT

Bands: 160, 80 and 40 Meters.

?
Download MS Word Log Sheet
Send logs to:

Tim Walker
19 Woodside Ave.
?Westport, CT 06880

All radio amateurs may participate and submit logs and all are eligible for an award. Non-member stations using pre-1950 gear count. All stations must submit logs to be eligible for an award and are encouraged to send a shack JPEG showing their vintage station. Electronic format such as EXCELä or (PDF, JPEG) scans via E-mail are accepted. Use the format posted on the AWA Site. Logs are due four weeks after contest. Plaques are to be awarded.

Objective: Contact the greatest number of AWA members or participating stations using pre-1950 design gear. The E-W multiplier has been dropped this year so all are on an equal footing. The 4 power levels have been retained. 20M has been dropped and the 40M frequencies have been shifted up slightly to the old novice band where slow CW is emerging again. When calling use “AWA AWA de W3GMS” for example. On contact, exchange the signal report, the year of equipment such as “TX36” for a 1936 transmitter and “RX 34” for a 1934 receiver. Send “MOD” for modern (after 1949) gear. And finally send your Input Power such as “10W”. Also send name and State or Country.

Frequencies: 1800-1820, 3550 – 3580, 7100-7125 kHz, +/- QRM Concentrate 160 meter contacts on the hour.
Equipment Multipliers MOD TX and RX 1
OT TX or RX 2
OT TX and RX 3

Power Multiplier 0 – 10 Watts Input 4
10 - 75 Watts Input 3
75 – 150 Watts Input 2
150 + Watts Input 1

N2BE contacts WT2W
N2BE Stn. Jones P-P at 6 Watts, Heath HB-10 (One OT), 1 MOD for 2 points
Power Multiplier for 6 Watts is 4
2X4 = 8 points

I am having trouble trying to download the log sheets. I couldn't do the BK ones either so made some up by hand and sent them in.
When I download these it defaults to Wordpad. When I look it is unreadable jiberich. So I tried downloading with Internet explorer and I keep goin round in circles (that would make a great song!) Where is a simple Jpeg when you need it. Can anyone help me figure this out.
I am NOT computer savy even though I still have my Vic 20.
I am on an aspire notebook using Windows 8.

Don - if you can view the log page full screen, just hit your "Prt Scr" button (usually along the top row of keys) and then open your MS Paint program and click "paste". You can then print out the file directly from Paint or use paint to crop out and eliminate what you don't want by cropping just the logsheet only.

GE Gentlemen, I received a good tip from W0VLZ and VE3AWA some time ago re: working a vintage rig into coax.I use the following link turns on the cold end of the tank coil: 80 Meters - 4 turns 40 Meters - 3 turns 20 Meters - 2 turns
There are two short lengths of very flexible 0 (zero) wire from the link to a 500 uuF, Lombardi, 2 speedvariable capacitor. One ground, one hot lead. The link forms a series circuit with this cap. Attached tothe above lash-up is my HB Collins coupler (aka-Pi network). I have found on 40 and 80 that the Pinetwork acts as a fine tuning arrangement. The link plus 500 uuF cap seems to do a bang up job ofmatching my 830B triode to RG-8. I hope soon to try it with my new 860 PA stage. I haven't tried it yetbut I believe I could bypass the Pi network.
All credit for this must go to Niels and Lou!
Roger/K1TG

Just in case I run out of QSOs (or crystals) I quizzed Tim a few weeks ago about the stated frequencies for the LC. He replied that these are recommendations to avoid QRM and in order to find each other. He did not indicate that these frequencies were firm requirements for countable QSOs. He seemed OK with starting in 7100-7125 but, if need be, shifting down to 7030-7040.

From Tim's response I concluded that you can make countable CW QSOs in other parts of the 160, 80 and 40 meter bands as long as all of the required information is logged.

(Tim, correct me if I'm wrong)

Matt, thanks for the report from WV.

Paul, yes, your recording would be appreciated and thanks for the QSO!

Paul noted some drifting during transmission. I am not sure of the source yet, but is either the tube or the transmit tub mica in parallel with the tuning cap. I changed the oscillator inductance from 16uH down to about 7.2 uH, which mitigated most of the hand capacitance problems I had before, making tuning to a specific freq. difficult. Parallel cap was changed from 400pF to 1000pF (both TX micas), but I noticed the drift with the original 400pF also. Of course, higher C/L increases tank current and larger fixed C will be shunting more of it too. More experimentation, but seems the rig is working acceptably.

Thank you both, Steve and Bill. The PDF files work fine. Steve's didn't show up on my computer till just now for some reason. I am good to go. Had Big Bertha (211 Hartley) running yesterday. I almost always get an answer with it and yesterday was no different.I had to quit the QSO because of strong QRM right on freq however the other end of my QSO said he could still copy. I enjoy running it. I have also been running the bug on my 1943 breadboard and wired it in parallel to my wooden key so if I get gefuddled I can switch instantly. Yesterday I said I didnt have a good 40M old RX. I lied! I have a homebrew regen using 1931 tubes and parts that works wonderfully so it is all set up ready to go when I fire up Bertha.
Jim Ve3DCX brought me a bunch of old QSTs including many 1929 ones and I have been reading through. One article in particular took my eye. Poor man mopa. It is not about a mopa at all but about getting crystal type stability out of self controlled oscillators. Much of it relates to how my last rig is done but he went much further in the article. It is very wordy (I write mag articles,(for CPApub. in the US) tech mostly, so I am always aware that to many words lose the intended audience) however it is also very informative and backed up by actual lab trials. It bears second look I think. The new rig here has no perceptible chirp and is not huge power but still seems quite effective even in less then ideal conditions so I was intrigued by his findings in the article. Meanwhile I am tempted to build a PA for the new rig and run it as a mopa. I wonder of it could drive a 211. I could call it David and Goliath.

What would be enuf to drive it say class C for instance? I have one more 211 socket and it is just begging to be used!
donVe3LYX
I suppose a pair of PP 45s would be more reasonable or even a single 45.
All set for the LC . Everything tested and ready to go. I may get a chance right at the start but more then likely will have to wait till 9pm, my time, to get serious but tomorrow should be fun till closing. XYL just reminded me I am booked for playing fiddle Sat night. I didn't plan that well!

Sorry Ron, Conditions were not great signal wise.here. I was going to be away this morning BUT with 7 inches of fresh snow overnite our morning plans have changed so I am going to play radio at least to mid day. After breakfast I plan to go on 80M with the breadboard station . It is rockbound so I will start on 3563-64 and if that is a wash, move to 3541-42. When 40m opens up usually 9:30 to 10;00 I will turn on the 211 hartley and the 56/58 regen on 7100 to 7110 and give it a shot. I wonder was I on the ARC5 when I got away. probably3550 to 3580 somewhere. (My military 1940s radios are only calibrated in 10ths) My No 19 set which I used with Johns QSO has a very distinct squack. Since it is an histotric radio I am not going to change that. The Arc5s have a chirp as well but it is different. Neil I would like to see if we cant hook up during the LC. We hang around the sam parts of the bands and I check RBN to see what you are up to and where.

Thanks to all for the great suggestions, explanations, etc.
I have had pretty good luck with using a sgl wire fed Hertz
(Windom) for years, but wanted to give a coax fed antenna
a try. Also, with a recently built 2A5 pentode osc (1933 RADIO
mag), I am having trouble getting decent output (abt 2w with
18w input) and wanted to be sure I had the proper matching
between the tank coil and antenna with coax feed. I will
try some of the suggestions and see what happens.

I am taking a coffee break right now but will be back at it by 9am. I currently have a 3542rock in the hole and a 3563 nearby if I need it.
Will run that set up till 9:30 then need another coffee.
donVE3LYX
Interesting comments Bill. I went through similar experience with my 47 self controlled osc. Finally got it working but tisn't my favourite rig. I have decided, now brace yourself lads, in my shack, Triodes are for oscillators , pentodes are for amplifiers. Although rockbound pentodes or beam power tubes seem ok. My boat and I am captain. I put a tuned circuit in the output as well as the one in the grid screen circuit. It seemed to help quite a bit but isnt a great rig. Certainly not as wonderful as the article I had on it (ECO) suggested. Not well suited to hi output use.
anyway back to the grind

The specs say 7.0W for class C telegraphy, but from my experience you want to be able to develop double that in order to compensate circuit losses, especially as you go up in frequency.
>
> I suppose a pair of PP 45s would be more reasonable or even a single 45.
>
A pair of '45s should do it, or a single '10 operated at its rated plate voltage. Some of the old-timers would use the same type triode for the oscillator as the amp, at reduced input, for greater stability than pushing a smaller tube to its limits.

Roger,

I was wondering where you were and hoping I'd run into you. I'm putting more time into the LC this time than I have in the past.

Yes put on the Utah Jr. K1TMJ was running one of those when I worked him this morning on 80M.

Since you'll be rock-bound, on which frequencies should we look for you?

I just got back home after a quick run to town and lunch. Will be back on 40m same area in the next ten minutes. Hopefully signals will come up a bit. I had to listen pretty hard this morning. I will be running Big Bertha and the 56/58 regen (which incidently can hear things my DX390 can only just detect as present. I can copy stuff on it that would be (and in fact were) in the noise on the DX390 and it is on AC power. If I had battrified it I would be laughing. Good RX!
Big Bertha helps keep the shack warm. I love running the thing. Roger go for it. I ran my old classic 1940s stuff last night for a bit. Now if Mike would pop on one of those TBX8s we could see how they sound. Good looking radios I think.

Bagged an NH with the 1943 ARRL Handbook breadboard rigs TX and RX. That was fun! Just had breakfast and am going to hook up the ARC5 80M. That is a noisy rig but the Rx Bc454 is not bad although a bit to the deaf side. Should have it going by 8AM , probably around 3565kcs. I will probably stay working till about 9am. If 80M craps out will fire up Bertha again on 40M although 80m is usually Ok till 930 or so. I know a lot of you are using you BK rigs and may wonder why I am not. These old rigs which don't work for BK don't get much chance to party(too much power input or too new) so I am taking them all for at least once dance during this event.

My TX was a Collins 310B (1947) for all QSOs, 80M and 40M.

Up until the last hour and a half my RX was the RAL shipboard regen (1936). Then the power supply for the RAL died (probably nothing too serious - the primary circuit opened up - I suspect the power switch.) So I warmed up the HRO-7 (1947) and finished up with it.

It was good to work you on both 80 & 40M this afternoon, Don.

Thanks, Your Collins has a neat sound. Easy to follow. Sounded real good on the regen and the BC454. Lou's TNT sounded real good. Impressive to say the least. We gotta get that lad a regen! Never had my ARC5 on CW before this event. I am sure it isn't their best mode but it sure was fun to running a pair (rx/tx)of ARC5 style vintage stuff. Does your Collins have MCW?
I started out midweek on the No 19 set and that was fun although its rx is so wide you could drive a truck thru. Not a good rig for CW in a crowded freq but we survived. I also used the Breadboard earlier but today it was doing a great job and I logged one almost immediately this morning. Running the 211 Hartley though is a blast for me. Only a handful of old parts and that big tube glowing. I love it. I should have put my handmade key on it as it is more responsive then the one I used. Never leaves your hand no matter what. I had it wired to the breadboard rig (hard wired , no plug in) along with the 1923 Vibo bug. I used the bug a bit midweek and yesterday but never got a contact with it. I had the wooden key parallel wired to it so if I got confused I could switch in a second. Oh yeah Larry when I worked you today on 40M I had just thrown the switch on the PSU and heard you so I was working from a cold start up which isn't really good but we survived. It had been on about 30 or 40 seconds when I started the reply.
Earlier this morning I worked WU2D Mike with the crystal controlled breadboard 80m rig. I had breakfast then and went down and switched on the 211 and the 40m regen and called. There he was. Right on 40M and I had just signed with him on 80M about 25 minutes before. And then there were you this afternoon. Almost the same. Good weekend! Thanks all. There is nothing like fun for a good time!

12379. Collins 4A Transmitter Schematic

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-01-19 13:39:34 UTC
From: dulmagedon@...
Topic: 12379 Message: 12379

I know I will probably never find one (but if you have one and want to part with it say so PSE) so I have decided my next project will be a Collins 4A transmitter clone. I happen to have the tubes, all but one in stock and have already built a 47 tubed oscillator so am familiar with that. Since its a rack mount I can buy the panel and the chassis (16x10x2?) from Hammond as well as the transformers. The Sangamo caps I don't have but think I could find them. The rest I think is available. Does anyone have a schematic or know where I could get one? I can probably figure most of it out anyway but it would be so much easier with a schematic. The 4A was a very low cost three tube crystal controlled transmitter circa 1933 with an on board PSU , one for the PA and a separate one for the osc. Might take me a year to collect the parts and build but perhaps it could be ready for the next LC event. I found lots of pictures. Dad was a Collins design engineer in the 1950s to 1962 so I gotta have something Collins even if a clone in my shack. Preferably while he is still living. (92) Also when I play fiddle at The 1802 Station on Fridays the fellow sitting about a foot away from me (Don Thompson) worked as tech for my Dads friend and fellow Collins engineer Floyd Rodin. Each engineer had his own assigned tech. Anyway, I need to honour them even if with just a clone. I knew so many at the Scraborough Plant (Collins Radio Of Canada) and last time I was there with my brother buying lab equipment they no longer used, many still working there came to see "The Dulmage boys " as we would sometimes go in with Dad if he had to work on a Saturday morning during the Avro Arrow radio project and the Gas Can Radio project. Good memories! I need to honour them and this seems one way to do it.

Don,

The 4A looks like a neat transmitter. Did you see the one on ebay recently? Price was $30K. I don't believe it sold.

For the benefit of others here's a summary:
>
> By J.B. Jenkins, W5EU and Gary Halverson, WA9MZU
>
> /Third in a series, this article describes the lowest cost transmitter
> produced by Collins Radio during the prewar years. While few of these
> transmitters have survived today, the cute little 4A is perhaps the
> most common of the prewar Collins transmitters./
>
>
> A Rig for the Times
>
> The 4A was Collins' answer to a low-cost basic CW transmitter that the
> average depression era ham could justify, according to the Collins
> ads, due to the fact that the combined cost of the components were
> greater than the purchase price, $58.50 with one set of coils, less
> tubes. A perfect companion for the National SW-3 which sold for under
> $15.00 at that time.
>
> The 4A was provided with a built-in power supply and used isolantite
> plug-in coils for each band (sold as an option: a set of two was
> $5.00). Rated at 25 watts, it used a 47 oscillator driving parallel
> 46's. An '80 was used in the oscillator power supply as the low
> voltage rectifier, and an 83 as the high voltage rectifier.
>

One quirk not mentioned... The 4A included no provision to turn off the oscillator during receive. Guess no one thought you'd be listening on your transmit frequency.

I researched the 4A when I was building my sorta Gross CW 25. See http://w0vlz.blogspot.com/search/label/1934%20transmitter

Here's what I found -

- Schematic: https://www.prismnet.com/~nielw/1934XtalXmtr/Collins4ASchemetic2.JPG

- Pavek Musuem article on their 4A: http://www.pavekmuseum.org/collins4a.htm

- Bill Orr's construction article from Nov1971 CQ detailing similar transmitter: https://www.prismnet.com/~nielw/1934XtalXmtr/50Watter.pdf

- Collins Collectors Association 4A Article:
http://www.collinsradio.org/cca-collins-historical-archives/the-equipment-of-collins-radio/historical-equipment/4a/

- Series of detail photos showing construction:
http://rockwellcollinsmuseum.org/artifact_collection/viewer.php?id=21&v=8

More information and help is probably available by contacting the
Collins Collectors Association. See http://www.collinsradio.org/

Good luck on the project. We'll look forward to hearing it next LC.

73,
Niel - W0VLZ

Neil, Thanks. Got it!
The No 19 is like that so if you are monitoring on an extra Rx it can drive you nuts but the worst is the ARC5s. I built the PS with a separate filament transformer so I could leave the tubes hot but kill all HV to the whole set. Then the trick is to REMEMBER to kill the B+ to your RX BEFORE you resupply the TX with HV. When using the ARC5 station on 80M Sunday I felt like I could use a couple more hands. Deafened myself a couple times.
I need a control panel I guess for it. Anyway I think the 4A is doable and one could come awfully close to identical with a bit of patience and some luck shopping for parts. I really appreciate the help with the schematic Neil.
30K? ! That like right now on Kijiji there is a HP No 19 for 6K. Second time for the listing. And PSU is homebrew. I guess I did well getting two for $100.
Anyway I like the look and simplicity of the 4A. I think I will give it a try.
Thanks again , DonVe3LYX

Well, that's a new one on me. I guess it depends on how you define "worth". There is no way I could afford that, but if I had the means some do I very well might grab it since I find something fascinating about it.

Lou - I haven't forgotten about our power supply discussion. Still feeling very overwhelmed and have not had bench space or bench time to pull mine yet. When I do, I will draw up a schematic for you.

From: Louis Vermond
Topic: 12389 Message: 12389

Hello,

I need a 6V battery for filament power. The current draw would not exceed 3 amps.

Six volt rechargeable batteries are not available in town. Would the following work without damaging the (lead acid) bat.? Using a 60 W bulb for example, drain the 12V down to 6Vs and, when necessary, recharge using a 6V charger. Would I have a 6V battery?

Out to lunch or not?

Tks, Lou

12390. UV-202 TX

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-01-20 21:22:39 UTC
From: mattgoff54@...
Topic: 12390 Message: 12390

In the process of augmenting my tx tube collection I ended up with a 210 and a UV-202, a UV-201A, and a "newer" 203a. I want to build a TX with the UV-202, along the lines of earlier components and construction, and circuitry where applicable. Earlier, that is, than "1929" era, if there is much of a difference. The tube just looks way cool. I have a small stack of QST's ranging from 1924-1938 and a 1934 Handbook, and it seems like the TNT's and Hartley's I see are running 210's or 45's, not many early articles Ive seen describing a 202 TX. I think the 202 was introduced in 1922? Any ideas are appreciated. Or am I crazy.

Matt

Congrats Matt, on the great additions to your tube collection. Don't know if this would be of interest, but in the May/June, 1924 QSTs, there is info on the Meissner osc, which uses 202s. It is an odd type circuit, but can be built. I run the 4-coil version on 160m, but so far have not been able to find a good 202 so am using a 1924 version of the '01A. I get about 2 watts out on 160 using an inv. L antenna. As far as I know there are only, maybe three, of these type circuits being used in the BK event....so its not a well known oscillator circuit. Oh, and Mike, WU2D, had an article in the AWA Review, I believe it was, a few years ago on this circuit....and he is one of the three running one.

Lou, it's the chemistry in the battery that determines the output
voltage, which, for a lead-acid cell, is roughly 2.2V when
fully-charged. I doubt it will deliver much current when discharged to
1V/cell. And if you try to use it that way you propose, you'll kill it
in short order.

Hi Matt,

Bill's suggestion is good. The other UV-202 era circuits were the Colpitts, Hartley and TPTG. I have attached a portion of a 1924 QST Hartley article. If you wish the entire article I will scan it and mail it to you.

As to pre-UX-210 parts, if you have or can borrow digital copies of QST 1920-'25 you would do well to read each issue looking for what parts were available as well as typical building methods. Because it's a 5 Watter (low power) early broadcast magazines would also be helpful in this as well.

GL, Matt.

I use and have for years the rechargeable Gel cells found in the million Candle power flashlights at CTC. The Lights are often on sale and under $20 , occasionally well under. I bring them home and remove the battery and chuck the light itself. takes but a few minutes. The voltage is on the box. The red ones are usually 6 volt. You also get a charger and a charge controller and plug in in the deal plus some extra cables. They work very well for running filaments (and that isthe only reason I have them. I get mine at Crappy Tire (Its a Canadian thing fellows) I think you have Crapppy tire on your town. If you would like I will get you the SKU number. A very very practical solution. I have no desire for anything else because it works so well.

Thanks Lou and Bill. I will research the Meissner, sounds interesting. I know its not really necessary but I do like the idea of a finished product that is period correct in all aspects. Guess I will have to get together a bunch of jars and get an authentic PS going. Maybe. I do have a few Model T coils laying around. Lou, the schematic in that article shows something common to most early ones Ive seen. That is, every connection on the coil is a "tap" via clip. I see ads for varying dimensions of inductance coils, many flat conductor, as if it was commonly a pre existing unit that one tapped for their needs. As opposed to winding your 1/4" tubing for whatever it may be.

Here is the last one I bought. Battery was 6 volts and more then sufficient amperage. When I bought it (I have bought two) it was on sale for around $20 so buying the lamps is often far cheaper then buying a battery. ALSO. Alarm companies keep the battery ies changed on Fre exit sign and they use 2 six volt rechargables of industrial quality. They have to dispose of them or does the building owner.often they are still good and I had for years gotten them for disposing of them They had so many though and not all were good disposing of the bummer made buying a light and removeing a brand new battery look cheap.

Might I suggest backing the hole with a piece of wood/plastic and filling the hole with JB Weld. Somecareful sanding and a repaint and you can't tell the difference. I worked a similar process on aNational PSK (pre-selector for an FBX). After repainting with Black crackle paint, the repair wasbasically invisible. Don't lay it on too thick, it may take two applications. Allow 24 hours dryingtime. It is quite hard when dry.
If the panel is Aluminum, I believe JB Weld is also made using made with Aluminum powder butdon't quote me on that. The steel powder variety should work OK.

Roger –

That is close to how I would do it. Except, I would clamp a thick piece of Teflon on the front so the epoxy would be flush and smooth with the front panel when the Teflon is removed. I would also try and bevel the back to keep the epoxy in place. Finishing to match then would be trivial. 73 – Mike

Well you could and it would look good from the front if you were careful but inside where you live, you would know it wasn't. I would remove the front panel, protect everything that isn't removable without damage and fire up the Hi Frequency Tig Welder which is what this QSL picture is off. and fill the hole and repair it. Then it would be all once piece and when done undetectable. Assuming it is the one with the aluminum front panel. Steel is similar process. and could also be undetectable The hard plastic one would probably be the biggest challenge to make a undetectable repair.

Hi Mike, I have never used anything on the, relying on some light sanding. I apply the stuff with a smallrubber squeegee. Possibly a putty knife will suffice. JB Weld is fairly sturdy even in thin sections.

In the case of steel panels, I drill the hole out with a drill bit big enough to make the hole roundand I sweat (solder) a sheet brass plug into hole. After cleaning out all the flux, I use JB Weld asa sort of body putty. In a word, it is miniature auto body work.

Roger – That is close to how I would do it. Except, I would clamp a thick piece of Teflon on the front so the epoxy would be flush and smooth with the front panel when the Teflon is removed. I would also try and bevel the back to keep the epoxy in place. Finishing to match then would be trivial. 73 – Mike Mike B. Subject: Re: [AWA Group] Re: Collins 4A Transmitter Schematic Might I suggest backing the hole with a piece of wood/plastic and filling the hole with JB Weld. Somecareful sanding and a repaint and you can't tell the difference. I worked a similar process on aNational PSK (pre-selector for an FBX). After repainting with Black crackle paint, the repair wasbasically invisible. Don't lay it on too thick, it may take two applications. Allow 24 hours dryingtime. It is quite hard when dry. If the panel is Aluminum, I believe JB Weld is also made using made with Aluminum powder butdon't quote me on that. The steel powder variety should work OK. Congrats Matt, on the great additions to your tube collection. Don't know if this would be of interest, but in the May/June, 1924 QSTs, there is info on the Meissner osc, which uses 202s. It is an odd type circuit, but can be built. I run the 4-coil version on 160m, but so far have not been able to find a good 202 so am using a 1924 version of the '01A. I get about 2 watts out on 160 using an inv. L antenna. As far as I know there are only, maybe three, of these type circuits being used in the BK event....so its not a well known oscillator circuit. Oh, and Mike, WU2D, had an article in the AWA Review, I believe it was, a few years ago on this circuit....and he is one of the three running one.

12413. ECO when?

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-01-24 00:31:02 UTC
From: Eric NO3M
Topic: 12413 Message: 12413

Both the 224 and 865 (screen grid tetrodes) were available in 1929. They are perfect candidates for an ECO (electron coupled), which I use in my 1930s style MOPAs with a 89 pentode. While the technology obviously existed at the time, I cannot seem to find any documents dating pre-1930 regarding ECOs. The earliest so far is an article by Grammar in Oct 1932 QST. There are no citations to any earlier work in that article, but by the discussion it sounds like the ECO was already well tested and established.

A generic web search doesn't bring up any earlier references.

Does anyone have any information, documents, etc., that reference an ECO circuit prior to Grammar's 1932 QST article?

Further digging found a Jan 1932 QST article by JB Dow, who cited and also authored a Dec 1931 article in the Proceedings of the Institute of Radio Engineers, "A Recent Development in Vacuum Tube Oscillator Circuits". For lack of that 1931 article and no further citations, based on it's title alone, it appears the ECO came to light sometime in 1931...

This is a timely thread! I built an ECO with a 42 tube sometime ago. I had a few contacts with it but found it unruly at higher power levels. The articles I had read in old QSTs and Radio news suggested that it should not be used alone like a self controlled osc but I had figured if it was as good and stable as sugested at moderate power it would probably be ok. Today long before I saw these postings I dug through my box of early 1930s tubes and removed the oscillator from the 42 tube cathode, grid, screen and built one using all the same parts mounted exactly in the same places using the triode section of a 75 tube then used the output to drive the grid of the 42 tube as a normal RF PA.. Wiring changes were minor and much need no change whatsoever. I am happier with the rig now as a MOPA but will explore further. I have not shut the door on the ECO but I had been unable to make it behave in a manner that I felt would be acceptable for daily use. I am curious about yours Eric and your experience. It was hard to change it out as I had high hopes.

Don

I haven't tested an ECO directly connected to an antenna, so no words of experience in that specific case.

The 89 ECO in my 80/160 MOPA is driving a 802 buffer. I run 300V (unreg) on the plate, 105V (reg) on the screen, and 45-50V unreg on the suppressor (this can be grounded, has little effect on performance but increases output a little). References note that if the screen voltage is supplied as part of a divider from the same supply as the plate voltage, voltage variations will track and have minimal effect on freq. changes.

The grid circuit in my ECO is a Hi-C Clapp, plate tank is low-C like any typical buffer/amplifier stage. I generally run the grid circuit at 1/2 desired freq. and tune the plate circuit for the second harmonic. This is referenced in Grammar's article as well, noting that the second harmonic output is nearly the same as the fundamental. This helps stability a lot. An op from the mid-west in a recent QSO commented that he couldn't believe it was a open construction, breadboard oscillator.

Regarding the 42, is it of the "screen-grid" type? 224 / 865 screen grid tubes can be used without neutralization, but the 46 and 47 (non-screen grid) need to be neutralized in an ECO. The 42 may be in the same situation as the latter. Check out Grammar's article (Oct 1932), he goes into great detail on neutralization regarding those tubes, as they fill the void in power class between the 224 and 865 at the time of the article.

Yes the 42 is a proper screen grid tube, forerunner to the 6f6 octal (electrically identical) but is a 6 pin. All the tubes for my 1930s "TWIN" station both tx and regen came from the same source. A 1931 Grimes bros set the clerk at the local Lowes gave me when he heard I was buying hardware for old radios. (Lowes still sells the brass thumb nuts etc) I usually build a neutralizing stub in when I first build a hi power RF device . It is sort of a minimalist method of neutralization but is easily adjustable and sometimes all that is required. This tube didnt require it so after a bit I removed it. The 42 is about double the power I think. I think an 89 is average of 1.5W and a 42 3.5W. I had no trouble getting it to oscillate etc but keying was a real pain. It had a very pronounced chirp and nothing I did seemed to help. More then once I worked on it all day. Playing with screen voltage , cap values etc etc and set it aside in disgust but I kept at it. The 1930s article I had read on it suggested that an ECO does not do well as a stand alone self controlled power oscillator but is more suited to exactly what you are doing. You know me, I had to try anyway but I can't say I wasn't warned. So when it came time to make the rig a Mopa I went back to my tried and true favourite, an old triode hartley osc running lightly loaded driving the 42. I do have a spare 42 so could have done an ECO driving a 42 but I whimped out Still the whole deal was interesting. I am currently trying to discern what the ECO advantage really is since I have no trouble with a triode osc whatsoever but hopefully I will get so I grasp that someday. In the meantime I applaud you efforts. From the reports you are getting, it sounds like you did it right!

Ok guys, bear with this 27 yr old newbies troubles. Although my iPhone and XBox are sometimes just as frustrating.

I succesfully got my Hartley running well enough to put on the air, using two globe '27s in parallel and about 180v on the plate at 28mA. I think about 4 watts out, no digital meter. Made a few QSO's despite my horrid antenna switching. So to get ahead of myself I thought I would try and run this output into a PA using a 210. Basic one tube amp, and I converted it to shunt feed as many do, moving the series cap from the coil tap and putting it at the plate, also the RFC. 400v on the plate. Also no external bias, the grid is grounded to the fil center tap via the grid leak and a RFC. So I threw it together, with not-so-correct cap values, but should work...I think. Coupled it to the Hartley using the oscillator's ant coil (4 turns on 80m). One end goes right to the 210 grid, the other through a cap to the fil center tap. Seemed to be able to get it neutralized using a loop and bulb on the plate end. But when i put the B+ to it and key the center tap, the plate current hits 70+ mA, without excitation and doesnt change all that much with various condenser settings. Keying the oscillator causes a very slight drop in plate current. Im obviously missing something. Please help!

73, Matt

Hi Matt,

Congratulations on getting the Harley running, and on making some QSOs with it!

I suspect you aren't getting enough drive to the '10 from the Harley with the type of coupling you are using. This would mean, among other things, that you won't develop adequate grid-leak bias for the '10, and as a result the '10 will draw excessive plate current.

Here is what I would do. Forget about using the antenna coil on the Harley to drive the '10. Instead, couple to the '10 grid through a mica capacitor in the .001 - 0.005 mfd range clipped to the Hartley tank coil a turn or two from the plate end of the tank coil. You can adjust the excitation by clipping up and down on the coil. You can also neutralize with another clip further down the coil toward the grid end. One end of a variable neutralizing cap goes to this clip, the other end is tied directly to the plate (or better, on the other side of the DC blocking capacitor) of the '10. You can adjust the neutralization by the position of this clip and the neutralizing capacitor adjustment.

Oops, I forgot to mention -

Also, since the '10 is running without any fixed protective bias, you'll need to key the '10 PA stage along with the oscillator.

Ok I tried the cap coupling method and the plate current is still the same 70mA when keyed. If i pop the grid leak off it goes to 0. Also that output tap wants to be where the grid/plate tap is or it makes the signal very rough. Dont know if thats normal. My tap is one turn to the plate side of center, out of 12 turns total.

Do you mean, if you let the grid of the '10 float for DC, the '10 plate current goes to 0? That's odd. What is the plate current with the grid of the '10 disconnected from everything, with plate voltage applied?

> Also that output tap wants to be where the grid/plate tap is or it
> makes the signal very rough. Dont know if thats normal.
>
I don't think it's "normal," but I don't doubt you, and again, I'm at a loss to explain it. In these rigs getting a T9 note can be a challenge. I'm not sure what you mean by grid/plate tap. In a Hartley, the grid is connected (for RF) at one end of the tank coil, and the plate to the other end.

> My tap is one turn to the plate side of center, out of 12 turns total.
>
Is that one of the places that makes the note rough?

I dont think a 10 can handle the drive of a pair of hot 27s . I think a 27 is electrically close to a 56 and I have played quite a bit with them. The 10 is becoming almost a restriction rather than a boost. Pull one 27 (most PPs you can do that) and see if the behavior is any different. That is what I would try costs nothing and will give you an idea if that is the problem.
I could be wrong but if I had a pair of good working 201As driving something it wouldn't be a 45 (a po-boys #10), it would be a 211. Never had a 10 but a 45 is a low cost alternative not THAT far off in power.

Larry,
With the grid attached to nothing the plate current hits 80mA. However, I have managed to notice that at a point on the neutralizing cap it shoots from 70mA to 12mA. About half the condensers range for each condition. At 12mA its oscillating nicely. At 70mA its just making my 210 unhappy.

If you have access to the QST archives, pull up the following:

Sept 1928 "The Oscillator-Amplifier Transmitter", Hull
Feb 1931 "More Power with Better Frequency Stability", Grammar

I haven't gathered what neutralization method you are using. Hull's final 210/210 circuit uses amp plate to osc tank (grid end) neutralization, Grammar uses the more common split amp tank to amp grid neutralization. I'd recommend the latter, keeps neutralization isolated to the amp circuit. The other method requires re-neutralizing every time you change *any* taps on the oscillator tank. If you're amp tank is currently single ended (one end RF grounded), lift that end of the coil and the capacitor from ground. The capacitor will remain "floating" (still connected to the tank coil in the same way though). Add a grounded tap to the amp coil, anywhere from 25-50% from the formerly grounded end. Connect your neutralizing cap between the formerly grounded end (either at coil or capacitor) and amp grid. See schematics in the above Grammar article, but adjust for parallel feed if that's what you're using.

The coupling cap between osc tank and amp grid should not be that close to the osc coil ground tap. RF voltage close to that tap will be almost nil. Best place for an output tap is usually at the far plate end or at most a couple turns down. If the note is rough, try adjusting the osc ground tap, osc grid leak resistance, and/or osc grid coupling capacitance. Maybe the osc is overdriving the amp?! if the tap needs to be that close to RF ground potential.

As Larry already noted, you need to either key the stages together, or use grid bias voltage on the amp if only keying the oscillator so that amp plate current stays in check. Disconnect or uncouple the antenna. If the amp tank tuning does not produce a setting where platre current is almost nothing, maybe the tank is not resonant...

Don, interestingly enough I thought the same but since Ive seen articles showing a 10 driving a 10 I thought id try. I actually have the 210 socket sitting on top of the socket for what I had originally been trying to use, a uv203-A.

But I dont think Im close to actually driving an amplifier. Just keying the amp without excitation I either have tons of rf on the amp's coil or its running 70mA and dead.

I missed this post last night,Eric but am up for a test anytime you wish. Even this morning.
In my understanding of all this the whole purpose of a Mopa is to allow the oscillator to run with a very light load which keeps changes and heat to a minumum. To have it run more or less as we would have an receiver oscillator run and use the PA side of the mopa to lift the power up to a normal level. Ths eliminates a lot of the chirp issues etc and because the osc section is running very lightly loaded heat in the tube , the resistors and dont for get the tuning coil is minimal and stabilty is improved. Otherwise there is little advantage to the deal because of all we want is power people built crystal controlled single tube 813 rigs in the past that were workable. The fact that we know with a bit of good fortune and careful design we can build a single tube self controlled osc /tx that will have pretty decent performance. Lou's latest TNT is one that comes immediately to mind as it sounds almost "commercial". The last hartley I built a week or so ago and tested is also devoid of any noticable chirp so making it a Mopa would be of no advantage unless I simply wanted to increase power and use it as a stable VFO. Otherwise it holds no magic solution. I have one I built for the 4 tube transceiver that works well. I used basically a rx osc design using 1/2 a 6sl7 and it drives the grid of a 6v6. It is very stable almost to the stage of wondering is it just a fluke. The mopa I just finished I couldn't get it to be have as an ECO as it had a bad chirp no mater what but good power. Now as a mopa it is pretty good however it cwetainly has no more power and truthfully probably a bit less then it did before but I can use it on air without embarrassment. It has enough power to be useful. The subject when applied to our small one tube txs is a bit more complicated in practice then would first appear. However I see you are a builder and waste no time letting the grass grow under your feet so I know you will be fine and will figure it all out to your own satisfaction. My Dad an old time E Eng and former Aircraft Radio designer for Collins told me when he was in his 80s. "Try everything you think of." Best advice he ever gave me.

OK. It's expected behavior that the plate current shoots up to the moon with the grid floating. What's not expected is that with RF excitation to the grid, but with no grid leak to complete the circuit to ground (and so develop grid-leak bias) results in no (or low) plate current on the '10. That's got me stumped.

I disagree that a pair of '27s are too much drive for a '10. You need to hit class C triode amplifiers pretty hard with grid drive, and you don't want the oscillator working too hard to do so, or stability will be little better that with the oscillator driving the antenna directly. Many MOPA designs of the time used the same tube (or at least a tube in the same power class) for the MO and the PA.

Hi Matt et all, I haven't read all of the comments, yet, regarding your 210 PA, but before I do, I wanted to very strongly echo Larry's comments on the grid bias situation. At 70 ma. of plate current, you are grossly exceeding the maximum rated plate dissipation, unless the plate voltage is less than ~ 200 volts. In addition, I suspect that the 70 ma figure almost certainly exceeds the max allowable DC plate current, for the 10. The 10 WILL undoubtedly suffer damage or be completely destroyed, if this situation isn't corrected, ASAP!!! (before doing any more testing). I can't quickly find the recommended class "C" data, for the 10 (only class "A" & "B"), and I wanted to send this info asap. That said, a look at the data, for the 10, indicates that a bias of about minus 30 volts of fixed bias is required to hold the plate dissipation, at a safe level, with no excitation applied. The alternatives to supplying the suggested fixed bias (as Larry has previously mentioned), is to key only the amplifier stage, allowing the oscillator to run continuously during transmit periods (turn off B+ to oscillator and PA during receive periods to avoid QRM), or to key both stages simultaneously. GL & 73 de Ron

Thanks for all the advice guys. Last night after working Eric's MOPA I tried a few things to sort it out with plate supply from my '27 oscillator, at 180v. Kept the tests very very short so hopefully the tube isnt hurt too bad. But I thought Id better be safe so I pulled the 210 socket off and stuck the 203a back in there. With that tube I still saw plate current in the order of 40mA when keyed with 400v and not a fully lit filament (which may be bad practice I dont know. Havent got a good 10v @3.25A).

But I may be getting somewhere...I'm very new to amplifier design so neutralizing procesure was kind of a guess. What I had tried before was to light the PA tube, and with the B+ to ground closed, feed it rf from the osc, and tune the PA tank into resonance while adjusting the neut cap to kill it, tune around and repeat until theres no rf on the tank. Then when I put B+ to it, it oscillated like crazy. So I tried letting it oscillate and adjusting the neut cap until it was killed, tuning the tank cap and repeating, and now I seem to be getting good rf through the amp from my osc. The 203-a draws 20mA keyed and about 40mA with excitation, no anywnna coil in place.

The recommendation of the tube manufacturers is to run the filament between +/-5% of the nominal voltage. The high end will shorten the life of the tube, and it may increase the life of the tube to run just a bit lower than nominal, with thoriated-tungsten filament tubes like the 10 and 203A. I seem to recall there are failure modes that will shorten the life of the tube when running below that range with plate voltage applied, though - definitely with oxide-coated and indirectly-headed cathodes, but with thoriated-tungsten as well.

The 203A, being a higher-mu tube than the '10, will not run as "hot" under zero-bias conditions, all else being equal.

It sounds like you're making progress. I would have started with the neutralization exactly the way you did, but I remember reading in the period literature (MOPA lore) that the final adjustment needs to be performed with the PA operating.

Matt,

I've been following the thread of advice you've been getting on your MOPA, and I'm attaching to this message a scanned copy of an article I wrote for Electric Radio Magazine, # 265, June 2011, pages 9 to 21, "Tinkering with a 1929 MOPA." I started off recreating as best I could the MOPA described by Ross Hull in QST, September 1928, "The Oscillator-Amplifier Transmitter." As described in my article I found it to be a pretty poor performer. The amplifier, even with 45 volts of battery bias as Hull designed it, was working more in Class AB2 than in Class C, and its output at the 10 watt input level specified by the AWA for the Bruce Kelley contest was only 2 watts on 40 and zero watts on 80! I made some improvements on the final amplifier bias scheme and tank circuit, among other things, and eventually got the amplifier into a Class C mode with efficiency in the 57% to 65% range. You can read the story for yourself, and it may give you a few ideas for working on your rig.

Best of luck!

Jim Hanlon, W8KGI

Matt ... before you get too far along, you must be sure that the amplifier is unconditionally stable. It should not oscillate on its own under any conditions. If it is, you may need to look at your parts placement and lead dress, bypass caps etc. Is it possible for you to post a picture?

As I mentioned earlier, these things take a surprising amount of drive so it's unlikley that you are over-driving it. I found that the top of the oscillator tank gave me max drive and my '10 needed it all.

My approach was to get the oscillator keying as cleanly as possible and then feed the amplifier. Any improvements in keying from that point, were adjustments in the amplifier....plate tank tap and the grid leak.

I used a 50pf for neutralizing and found that it required about 20pf only with a fairly sharp 'sweet spot'. I didn't find any difference in the neutralizing setting between no B+ and full B+.

Hi Matt, I did a bit of research, and learned that 70 ma is probably not a sure fire, quick death level, for the 10, although it does slightly exceed the "typical operation" level (60 ma) that appears in the 1936 ARRL handbook. I erroneously believed that the limit was ~ 50 ma.--my error.
 However, the max plate dissipation rating (15 watts, as per info in the 36 HB), is being exceeded, if the 70 ma of plate current is occurring at a plate voltage much higher than 200 volts, when no RF output is being delivered to a load. A series string of 9 volt batteries (2 for 1$ at Dollar Tree stores) will provide a suitable fixed bias source. Excessive plate dissipation can damage a tube, if sustained for any substantial length of time. Your neutralization procedure sounds ok EXCEPT for the B+ to ground part, which can upset the apple cart. To achieve accurate neutralization, the B+ lead should be disconnected and remain an open circuit, for this procedure. Be certain to keep the grid and plate circuit tanks in resonance. There will be some interaction between the tuning of these tank ckts, and the neutralization adjustment. Plate neutralization is more satisfactory than grid neutralization, especially when grid current is being drawn, as is the case for class AB2, B, or C operation
 IIRC, the permissible tolerance for filament voltage, for a thoriated tungsten type filament, such as the 203 has, is + or -   5% . Operating the filament outside of this range is a sure fire recipe for disaster, according to my reading. (no personal experience--I took their word for it!). You could use commonly available 12 volt xfmr (or 2 series connected 6 volt xfmrs). with a resistor added, in series with the primary (or secondary) winding, to drop the voltage output to 10 volts, for the 203. This method will also provide an automatic soft start function, for the filament.

Thanks Jim for the article. I printed it out and will give it a read, looks very interesting.

I dont have access to the full QST library, just the vintage hard copies I have. The design Im using comes from an article by Grammer in QST August 1931, "Adding an Amplifier to the Low-Power Transmitter." I will post a picture as soon as I figure out how to attach one in this thread.

I will go back through and recheck my neutralizing with the B+ open to make sure the PA isnt oscillating. Who knows maybe today it will be hi-hi.

Though I guess trial error will tell Im not yet sure if im better off using the 210 or the 203a. But the latter does look impressive if nothing else.
I do need to get the bias figured out so I dont have to mess with keying everything at once. And a good filament supply sounds like a must. I tell you, the 210 and, even more, the UV202 are rather bright with even 7v to them, let alone 7.5. Normal? Kind of scary, I dont want to have to replace them.

I read the whole thing. Very interesting. There is an assumption that everything done back in the day in a magazine was the pinnacle of perfection. Not always so.
We would do well to remember that. A couple of things I do not understand . One is the obsession with no 10 tubes. As good as they are they are not the only tube to use nor do they posses any "magic "qualities. The other is the assumption that only voltage that shows up on a DC voltmeter is affecting the grid and it relationship.
Also one should remind us that digital Multimeters around RF fields such as we see in our self controlled osc are not capable of meaningful readings. .

My friend Ken VE3GEM just gave me a heads up on this one. I already have two of them and so will exercise a bit of self discipline however this is an operational station on 12 volts for 80M and 40M and will sneak into the top half of 160M as well. I use mine all the time including some during the LC event. With a very slight no soldering mod it becomes a very practical daily set. In fact I am selling my DX60B and HR10B which it as completely replaced. (so if you know anyone looking , before I list them publicly contact me). This is a Mk111, last production. PSU is 12 volt dynamotor and the control box is also there as well as a 8ft whip antenna tuner.(variometer) He has other stuff listed and I am after the proper CW key just so U all know.

Anyway. maybe there is no interest however I use mine every single day. and my spare is awaiting its turn perhaps. Mine is a MKII. This is a Canadian version which is slightly different but not significantly from the British sets. They were Armoured Vehicle radios here .

How long does it take a BUG to build a simple keyer? Apparently, about six weeks! Too much other stuff to do...

Anyway, I plan to be on this evening, 3565 plus or minus, probably on the top of the hour at 7 and/or 8 pm eastern (0000, 0100z). This is a test of the new HV keyer before I pull the power supply for modifications. If anyone has the ability to make a recording of my signal, I would like to hear it. I am also playing around with higher voltage and lighter antenna coupling. At the moment, the rig is sounding a little more whoopy-warbly than usual. :-) I have no idea why. It has different moods...

Jim that is an interesting article. Obviously these rigs arent always and werent always great performers, but admittedly I hadnt given much thought to the possibility that not all the designs described in the various articles were the best by even the contemporary standards. I also hadnt really thought about making my MOPA efficient enough for the low input levels required for the BK.. Which brings me to a question, which might be a silly one. How does one calculate the input power for multiple tubes, such as in a mopa or my parallel Hartley?

That article also made me think about my bias so I tried an external bias of various voltages. It does help to ensure the grid is indeed getting a *negative* bias. The C bias on my heath supply is sketchy and wants to fluctuate so Im working out options. 9v batteries may be the way to go.

In playing with this thing the last few days Ive noticed a few things. One is that the hartley really doesnt like losing its antenna coil. Even with the coil swung full away and the antenna switched to another rig at the coax box its providing some kind of counterpoise effect or some such thing. Removing the antenna leads even when swung away causes the sig to go rough. Things get worse when tapping the osc tank for the amp. If i purposely make the amp oscillate by itself the signal it produces is clean. Neutralized and excited by the oscillator the signal is somewhat garbage. And by garbage/rough I mean the wave has two tones and listening on AM its rather buzzy.

I thought about trying a totally different approach to the problem.
Make a single triode oscillator and get it running well. Then make a double 10 (or 45) amp parrallel or pp as you desire. Make sure it is stable then connect the two with a two turn loop to a 2 turn loop and try that. For my old rigs as per your coax related experiments I use lamp cord (75 ohms approx) and always have at least 4 feet of it connected to my rigs. It really helps even with single wire antennas. If you worked me on 40M in Linc Cundall you worked that for sure. I have been where you are with all those difficulties BTW and slowly worked my way through it. Although not with a 27 10 deal but I understand first hand what you have said. If one hasn't been there themselves then it probably doesn't make much sense. Not as easy as it is thought to be. Talk is cheap. Experience is sometimes painful but good. Keep at it. You'll get it good. Many times I felt like chucking the whole deal but eventually got it done. I set it aside several times. Still have another one I built to sort out. (6bl7 mopa) The concept may be slightly overated. There is an article in a 1929 QST called Poormans Mopa which is really not about a mopa but deals with all these problems which I found very helpful in my case.

Matt,

I'm glad you found the article interesting. My feeling, after I got through playing with Ross Hull's 1928 MOPA, was that the "PA" was operating more as an isolation stage than as a "power amplifier." It probably made the signal a bit better, but not louder.

As to your power calculation question, we always calculate the "power input" to the output stage of a transmitter. In the case of a single or multiple tube Oscillator transmitter, like my UX-210 Hartley or your stand-alone Hartley with a pair of 27s, the power would be the product of the key-down plate voltage and plate current. In the case of your MOPA, it would be the product of the key-down plate voltage and plate current to just the final amplifier stage, regardless of how many tubes that stage is using.

As to bias, as you found in the article, I'm using a combination of 45 volts fixed, battery-bias, and grid-leak bias derived from the Class C amplifier's grid current flowing through the grid leak resistor. The battery bias is enough to keep the 10 from running excessive plate current with no drive applied from the oscillator. The additional grid-leak bias gets the tube into the desired Class C operating range. For what it's worth, my 1931 ARRL Handbook lists the following operating conditions for a '10: Class A audio frequency amplifier, Plate Voltage 425, Plate Current 18 ma, Grid Bias - 39 volts: Class B RF power amplifier, particularly as a linear amplifier for modulated radio frequency, Plate Voltage 350 volts, Plate Current 30 ma, Grid Bias - 50 volts; Class C Oscillator or modulated RF power amplifier, Plate Voltage 350 volts, Plate Current 60 ma, Grid Bias - 100 volts. So my 45 volts bias is just a little shy of the -50 volts recommended for Class B operation. Usually Class B stages are biased just at the point where the plate current is cut off; they conduct on one half of the grid-drive cycle and are in cut-off on the other half of the cycle. I'll also note that the three rigs shown in the 1931 Handbook using a 10, a TNT oscillator, a Hartley oscillator, and the two-tube, 10 Hartley oscillator, 10 amplifier MOPA, all specify 500 volts despite the 350 volt rating they give the tube earlier.

My 1952 ARRL Handbook has the following ratings for a 10Y: Class C Amplifier - Oscillator, Plate Voltage 450 volts, Plate Current 65 ma, Grid Voltage - 100 volts, DC grid current 15 ma, Grid driving power 3.2 watts, Power Output 19 watts; Class C Amplifier (telephony), Plate Voltage 350 volts, Plate Current 50 ma, Grid Voltage -100 volts, DC grid current 12 ma, Grid driving power 2.2 watts, Power Output 12 watts.

As to your experience with buzzy, two-tone, and rough signals, I'll have to defer to some of the other folks on this list who have more hands-on experience with these rigs than I do. The stand-alone Hartley might be coupling some RF into its power line feed, either through the filament or plate circuits, which would cause the rough note. The two-tone note in the MOPA might also be due to some unwanted coupling. I think that's part of the reason why Ross Hull found it better to shield the oscillator in a kitchen kettle. If you have an oscilloscope you might want to look at the waveform of the oscillator plate signal when the MOPA is buzzing. It might give you some clue as to what is going on, or it might just confuse things since the oscillator and amplifier are probably pretty tightly coupled anyway.

Have fun!

Jim, W8KGI

12458. MRHS Mini Night of Nighst / 600 Meters in 1972/74

Topic: 12458 Message: 12458

Pse check these recordings of QRM, '20ish sounding notes, etc on the 600 meter coastal freqs from early 1970s.....comparatively high tech days over the early sigs and equipment. Sounds like a BK on steroids. These sigs were received in Europe. Numerous other recordings of coastal stations are at the Maritime Radio Historical Society web site. Also, be aware, the MRHS is having another Mini Night of Nights with activity concentrated on MF freqs of 426 and 500 kc. US and Canadian Amateur MF stations will also be active. Listen for KSM on these and other HF coastal freqs. (See web page for freq list).

http://radiomarine.org/audio/list?panel=pab1_13#pab1_13

Link to the Announcement of the MRHS Mini Night of Nights and Newsletter:

http://campaign.r20.constantcontact.com/render?ca=9a7c8d0d-9989-495c-943b-765f413b516e&c=87e94620-790b-11e3-93dd-d4ae5292c4bc&ch=88dd6a20-790b-11e3-9409-d4ae5292c4bc

Its real neat to use the 'ear filters' and copy down some of the calls.

1929 QST has a 10 /203 rig. (which I would probably fudge to a 45/ 211 to fit my junk box)
Article is called "Crystal Note Without a Crystal" january 1929 page 17.
donVe3LYX
As for osc /amp crosstalk in a mopa. I reversed the tank cap leads on one of the tanks. Reduced the cap feeding the amp grid. Installed a serious RFC in the B+ to the osc as well as the one to the B+ in the Amp and eventually I got rid of it. It was not easy. They should probably be shielded , both osc and Pa or else far apart. It is I think exactly what you surmise it is. two signals. I came to the same conclusion.

Hi Matt, The input power is calculated by multiplying the final amplifier plate current (total for all tubes if there are multiple tubes in power amplifier stage), in amperes, by the plate voltage. If I understand correctly, your grid bias voltage is probably increasing when drive is applied. To prevent this, you must use a bias supply that can "sink" current. Otherwise, the flow of grid current will cause this phenomena. The easiest way to do that, if being period correct is important, is to use battery bias. A common cause rough signal, with a Hartley, etc. oscillator, is excessive feedback. In the case of a Hartley, the amount of feedback is established by changing the position of the cathode tap, on the oscillator tank coil. GL & 73 de Ron n4v

On Thursday, January 28, 2016 7:11 AM, "dulmagedon@yahoo.ca [AWAGroup]" <AWAGroup@yahoogroups.com> wrote:

I thought about trying a totally different approach to the problem.
Make a single triode oscillator and get it running well. Then make a double 10 (or 45) amp parrallel or pp as you desire. Make sure it is stable then connect the two with a two turn loop to a 2 turn loop and try that. For my old rigs as per your coax related experiments I use lamp cord (75 ohms approx) and always have at least 4 feet of it connected to my rigs. It really helps even with single wire antennas. If you worked me on 40M in Linc Cundall you worked that for sure. I have been where you are with all those difficulties BTW and slowly worked my way through it. Although not with a 27 10 deal but I understand first hand what you have said. If one hasn't been there themselves then it probably doesn't make much sense. Not as easy as it is thought to be. Talk is cheap. Experience is sometimes painful but good. Keep at it. You'll get it good. Many times I felt like chucking the whole deal but eventually got it done. I set it aside several times. Still have another one I built to sort out. (6bl7 mopa) The concept may be slightly overated. There is an article in a 1929 QST called Poormans Mopa which is really not about a mopa but deals with all these problems which I found very helpful in my case.

like the new picture.

I have been working on a new antenna. Inspired by Neil's vertical. I bought the fiberglass tent pole sections

and made sure they were the ring re-enforced as he said. I fastened them altogether with fiberglass resin. I had 22 feet in total. I then machined a chunk of hardwood dowel to fit in the top end and purchased a 11 meter marine style fiberglass whip. I bored a hole in the top of the hardwood dowel and inserted the marine whip (8 footer spiral wrapped) I soldered a wire to the fiber whips wire then spiral wound it down the 22 foot pole stopping about shoulder height for me to make a tappable loading coil. I ran out of wire for now and so will continue next week. I will paint the finished deal with resin to keeperfromfloppen. I have used a 20M vertical here for years (25 or so) with very good results and built it what I call Marconi style with a metal stub driven straight down directly under the antenna and connected to coax braid. If this one works as well as the 20m I will be fine. I can talk anywhere in the world on it and have, on my TS830S barefoot. In decent conditions of course but have busted more then a few pileups with it so have high hopes for this vertical. It should be good on 80M (loading coil in) and good on 40m loading coil out. Might need some rubbing to get it where I want but I am hopeful.
It is very light. I have the spot picked out and the metal ground stake installed. It will be guyed to nearby cedar trees. I am hoping it will replace my 40/80 inverted Vee for studio A (upstairs)

You may also want to keep the inverted V. It will be better for working closer stations (like me, for example), while the vertical, because of the lower takeoff angle, will be better for stations farther away.

12472. For Sale: Original early 1930's HB Receiver and Transmitter

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-01-30 21:48:34 UTC
From: Whitebear1122
Topic: 12472 Message: 12472

I am selling my early 1930’s 80 meter cw station. I bought this from a fellow who got it from the estate of the OT who built it back in the early 1930’s. I’ve probably had it for 15 years. I looked that transmitter and receiver over from top to bottom hoping to find the OT’s call sign written in there. I couldn’t find it. Maybe you can. I planned to restore it and put it on the air but I never got around to it. I know there is real 1930’s electrons stuck in the tubes and wiring. The transmitter uses a nice big fat crystal so I know it was early 30’s. The OT’s receiver I believe is the ARRL Rationalized Autodyne by George Grammar, and that came out in QST January 1933 so I’m thinking 1933 to 1934. The set up is for 80 meters. I put pictures of the transmitter and receiver up on photobucket.com at this location: http://s1140.photobucket.com/user/651daisy/library/1930s CW Station <http://s1140.photobucket.com/user/651daisy/library/1930s%20CW%20Station> for your viewing

This album shows several pictures of the receiver and the transmitter.

On the transmitter, the plastic supports for the 80 meter coil long ago disintegrated. The transmitter came to me with the coil laying flat on the transmitter because the plastic supports disintegrated and the coil just laid down as it sat on the OT”s shelf forever. I bagged up the coil in a Baggie because it can be easily restored. The coils are plug in coils so I imagine this transmitter can be made to work on 160m and 40 meters as well. Just a guess.

The receiver has a snazzy National teardrop style vernier dial on the front. It has two Hammarund ceramic plug in coils marked 3500 on them.

I don’t know anything else about them. They’ve been sitting on my shelf for years. They would be fabulous to restore and put on the air if you want. If not, they have a lot of original 1930’s vintage parts in them if you decide to build your own transmitter and receiver. A lot of these parts are “unobtainium” these days

Asking $200 for the pair plus shipping. Thanks, 73, Scott WA9WFA

12473. For Sale: Rationalized Autodyne Regenerative Receiver

Seeing what I believe is a Rationalized Autodyne regenerative receiver from QST January 1933. It is built in a nice wrinkle finish cabinet with lid. It uses a National SW-5 style dial and bezel. There is some damage to the dial plastic. It looks like the OT put it too close to the audio tube and it did a little melting of the dial material. Bet that really irritated him :) That’s what he gets for putting a hot tube that close to the dial :)

I bought this maybe 10 years ago with the plan to strip it for parts and build my own Rationalized Autodyne but I never got around to it. I put photos of it up on photo bucket.com here:

I really need to stop lookin at the ebay alerts. Anyway, In my quest for MOPA satisfaction Ive been reading a lot of material, and Ive noticed that all these power supplies in the old articles are running 20-30H filter chokes. Those who build their own PS with tube rectification, is 20 or 30 henries really make a difference compared to the 7H 300mA choke Im using? My PS is a Thordarson 700v ct at 70mA, an 80 tube, 7H choke, and two 7.5mf 1400vdc rated aerovox cans after the choke. Final output is 500v. Running the 203a on this and my MOPA chirps and drifts and sounds positively awful. 180v shared from the heath supply and its absolutely fine. Just wondering if im shooting myself in the foot with that power supply.

Matt,
1920s chokes were rated using a nominal system. A "30H" choke is actually more like 10-15 henries rated by the modern system.
Chirping is often the result of unstable voltage during keying. Because you are using a choke input filter in your power supply, you must have a bleeder resistor or some other means of establishing a specific minimum current draw from the power supply during key-up conditions. This is to prevent the key-up DC output voltage from soaring to the transformer peak secondary voltage.
The magnitude of this minimum current is determined by the inductance of the input choke.The following formula can be used to determine this current:I = E/(L*1.131)
where I is current in milliamps, E is voltage in volts, and L is inductance in henries.

There are chokes available called swinging chokes which are designed to have a high inductance at low currents in order to reduce the amount of power wasted in the bleeder resister for a given physical sizer of choke.

Jon

From your description, it sounds like your power supply filter is choke-input, i.e., no capacitor directly from the rectifier cathode to B-. If that's the case, there is an important relationship between the minimum, i.e., key-up load current drawn from the supply, and the minimum acceptable inductance of the filter choke:

critical inductance (H) = load resistance (ohms)/1000

The output voltage of a choke-input filter is supposed to be 90% of the RMS voltage from the plate transformer (from 1/2 the full secondary if center-tapped and used in a typical 2-diode full-wave circuit which you have), minus resistive losses. What happens, though, is if the inductance of your filter choke is below the critical value for the load, the filter thinks it's capacitor-input and the output voltage soars up to 1.4X that RMS voltage. If the filter is doing that on key-up, every time you depress the key the power supply voltage will swing from a high value down to a much lower value.

That could be contributing to some or all of the chirp. The drift is probably because you're running the oscillator at a higher voltage and current (=power input), and there is more heating of the tube and components. You could be having other issues like RF mixing with power-line frequency energy in your homebrew supply that you're not getting with the Heath supply. If so, that will make the note rough.

I've found choke-input supplies to be a bit of a pain, because you either need a swinging choke (which has a much higher inductance at low current that at maximum current), a huge choke, or to waste a lot of power in a relatively low-resistance high-wattage bleeder resistor. If

you can maintain the Lcrit (critical inductance) value, though, they provide much better regulation than a capacitor-input filter.

What I've been using instead in recent times is a resonant filter, which looks like a choke-input filter with another (non-polarized) capacitor across the choke whose value is such that the combination capacitor and choke is parallel-resonant at the ripple frequency: in the US 120Hz if it's a full-wave supply, and 60Hz if half-wave. It preserves the advantages of a choke-input filter without needing to worry about "going critical."

73,
-Larry/NE1S

Matt,

1920s chokes were rated using a nominal system. A "30H" choke is actually more like 10-15 henries rated by the modern system.

12486. Re: [AWA Group] Filters and other Q's

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-02-02 19:50:46 UTC
From: Ron Barlow
Topic: 12478 Message: 12486

Hi Don, To add a bit to Larry's excellent info and suggestions, I believe that I read that the reason for the high inductance choke use, in the days of yore, was based on economics. It was less expensive to construct chokes that had mucho inductance, vs high capacitance filter caps, in the olden days. As an aside, one of the drawbacks of this choice would be that a choke having lots of inductance, would also have a relatively high value of DC resistance. Thus, the regulation of a power supply that has such a high "L", low "C" ripple filtering network, would be somewhat poorer than an equivalent (similar amount of ripple filtering) low "L", high "C" filtering network.

In your case, however, I believe that a major source of your woes, is probably due to either a very low value of bleeder current, or no bleeder load at all. Otherwise, your power supply voltage would not be soaring to 500v, with a 700 volt CT power xfmr/full wave rectification, in place. You didn't mention the full load power supply voltage, but I suspect that it is in the neighborhood of 300-320 volts, maximum. Such a voltage change (500 to 300) is a sure fire recipe for chirp problems. A sufficiently "heavy" bleeder load should improve the regulation, significantly. The use of a solid dielectric (padder) cap(s), as a portion of the resonant tank circuit, may be the chief cause for the drift problem. All of the mica/silvered mica, etc., caps that I tried in my experimental power oscillator circuits, resulted in excessive chirp or drift. Replacing these solid dielectric caps with an air dielectric cap, in my power oscillator circuits, yielded a much more acceptable level of drift, and/or chirp. The internal capacitor heating would not be as severe at the lower (180 volt) plate voltage, but may become a larger issue at the higher (300v ?) plate voltage. YMMV!

I'm not sure about thoriated-tungsten filaments like in the '10, but
with oxide-coated cathodes (directly and indirectly-heated) I've heard
applying full plate voltage before the cathode is up to temperature can
strip off the emissive material from the cathode, after many off-on
cycles. Of course, this happens all the time in consumer-grade radios,
and low-B+ rectifier tubes, and those tubes last a long time.

Either way, it's "best engineering practice" to have the tubes at
full-glow before applying plate voltage. Why would you want to do otherwise?

My GDO is acting up so I was unable to test the antenna for freq although it should be in the window so to speak. My SWR meters are kaput as well. One doesn't respond and the other a Hamfest score never gives the same result on any antenna I have twice in a row so I cannot rely on it. Probably why it was a deal at the hamfest. However I hooked up my BareEssentials rig and put it on automatic, grabbed a SW portable and went for a drive. There is a spot down the road where if Icn hear there I can work most of you with the rig. That has been for me the definative test point. It was very strong there so I continued and over twice as far away as normal it was still strong. I drove around the lake and usually lose the signal on that back side but it was strong and not when holding it out the window which I used to hve to do but with it just lying on the dash so I continued another concession. I never lost the signal once SO if that is any representation of its 80M performance it is better. But it could just be because it is a vertical it has a low angle of departure too. I will need to log a few before I decide. Meanwhile I gotta figure out what went wrong with my Booton GDO. I thought it was the cable but it proved with the meter so it is something else but movement related. I got home returned to manual operation, ID-ed and QRTed all with in proper time (for those who wonder about such things).

Thanks all for the info, very helpful. I added a 35k bleeder and the regulation is much improved. Larry and Rons figures were about dead on and that took care of most of that awful chirp. This Im not sure what was causing the sig quality to go to crap in the amp but I have cleaned it up a fair amount by moving the tank coil tap closer to the plate side. This gives me about 40mA at keydown and somewhere around 10 watts out after I loosen the ant coupling to where it sounds decent. Slowly making some progress, might have it ready for a teat run soon.

Lou, I would like to make a chem rectifier as part of my very early CW setup...just to do it and see how those guys managed. Plus all that glass looks cool. A few weeks ago I saw on ebay a wooden rack with jars stacked two high. Probably around 50 jars, with the two electrodes and all. Didnt look right for batteries. Probably should have bought it. Oh well.

Thanks for the warm welcome!

A few of us might give it a try (K0SM, W2FU, NW2K) so I thought I would join up to learn more. We're all located within 30 minutes of the AWA Museum. No definite plans yet, just talk at this point. Talk is cheap!

Thanks again for the welcome!

73, Dean, NW2K

K0SM? Well, there is a call I haven't seen in a while. Andy may remember me from the early HSMS days in North America. Must have been about 20 years ago. Just checked my log. I've worked all three of you... NW2K on 80 and 40, W2FU on 160, 40, and 2, K0SM on 6 and 2 meters. :-)

Have fun building!

73,
Paul (aka Bugsy around here)

Did a little but more on it and some more testing. If the testing means anything it is quite a bit more effective then the inverted VEE . Now all I need is a real contact.
will be on 3561 again tonite Calling. 7 and 9 PM. for sure and will be fooling around a bit in a few minutes as well.
Here is a photo. Antenna is in a small clearing among a group of cedar trees. Only the marine whip part of it gives it away. Oherwise one would not see it even if looking at it not knowing.

I think about 9 watts in if memory serves me. Probably somewhere between 3.5 to 5 out of I am really lucky.
Been a long time since I measured this one. This is the rig I first worked you all on before you influenced me to try self controlled OSC. I still remember that first adventure. I still have it and use it. It is my upstairs shack.
I have my TS830S up here as well which I used with you and Joe not long ago. the only other rig up here is a homebrew SS crystal controlled TX which has never been proven on air. It has a permanent rock soldered in I think it is a 3.53 but would have to check. I wanted the vertical so I could use the Bare Essentails rig up here easily now that the inverted Vee is becoming seedy. It seems to be working anyway. I wish to thank you again.

Topic: 12535 Message: 12538

Good idea.This summer I went to a Military Museum Activity Day. I clip on my call sign tag when at tech museums because I often meet hams there. As we entered I saw there was a big signals display. As I approached two uniformed fellows I would guess to be my age or + approached me and motioned me aside. They introduced themselves as Hams and retirered Signals career folks. The bigger one turned to the side and asked me "Do you know Morse Code?" I acknowledged that I did although I am a bit rusty. He asked would I be so kind as to demonstrate two of the units they had on display. I obliged. They told me they had never actually learned it although the skinny guy did know a bit of what I sent so he must have had some experience with it. I knew from their calls they had been licensed a few years later then myself (VA instead of VE). I also got an invite to join their vintage group however my T shirt and a sign someone gave me for my shop wall reminds me not to. (WARNING, DOES NOT PLAY WELL WITH OTHERS!)
Back when I was first licensed I did a lot of CW ops. One night called CQ and got a very very faint answer from a JA. I could just hear him and that was all. We did the usual exchange and I went to sign. he asked me to continue and told me he was a Japanese Weather Researcher and had been cut off by weather and bad radio conditions and I was the first human contact he had had in 30 days. we went back and forth for about 20 minutes. I recorded some of it on a mini tape cassette. I still have the tape somewhere. In fact was talking with the XYL about it yesterday. If not for CW we would have had zip as phone would have been absolutely impossible. When I got my Advanced ticket I let my CW go. It was a dumb thing to do. Thanks to this group I have been forced to revive it and it seemed hopeless at first even for a few years but I notice now the rhythm is coming back. I had given up on it ever happening. I was never fast but I have many old QSL cards with a note on them saying "gud fist" I should have looked after that but didn't. I regret that now. It is good to see the US Navy getting back in the game. Hopefully ours will too.

WOW! Thank you, Neil, Mike & Garey.

As you may have picked up from http://www.ebay.com/itm/Reproduction-ca-1930-TNT-Ham-Radio-Transmitter-/262280927777?ssPageName=ADME:B:SS:CA:1120 there is mentioned in the description, "a design from Dave Ingram, K4TWJ, as presented in CQ Magazine in March 1989".

Neil, yes I would like a hi-rez scan of the article.

Again, tks all, Lou

From: dulmagedon@...
Topic: 12545 Message: 12545

I see SAQ is scheduled for a transmission tomorrow at 1800. Probably a tune , then a trial on feb 15 at 1000 and a broadcast at feb 16 1000 all UTC. I am going to try again with my SAQ SDR but I also have a converter built . My LF Regen doesnt go that low (yet) I think it is World Radio Heritage Day or something.
donVE3LYX
Lou Dave Ingram is famous for something else and I have built it but at this second cannot retrieve it to memory. AHAHA!!!!!!!!!!!!!!!!!!!!!!!! The MICRONAUT tranmsitter ! It just came to me and I have one!

Lou,

(Unfortunately I no longer have that particular issue)

Look also for the Jan '73 issue of CQ, pg 38-42+91. I wonder if this
Bill Orr article was the source for Dave Ingram's March 1989 article.

73,
Niel

12547. Copper / Wood epoxy

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-02-09 23:31:35 UTC
From: Eric NO3M
Topic: 12547 Message: 12547

Anyone have a recommendation on a good adhesive to bond wood to copper?

I recently put together a 210 Hartley to add to the growing '29 arsenal. Tank and antenna coils sit on a slide rack (same as a few Hull rigs). I wound a 1/4 in. copper coil for 160, 4.75 in dia., 14T, about 7 inch long. If everything is settled, excellent note and stability, but the slightest disturbance causes "wobbulation". Three thin slats of wood glued to the coil should fix that.

Antenna coupling coil / cap are mounted, but not wired up yet.

Well thats too bad. He is no longer on this earth so hard for him to defend himself however I don't believe he claimed to have invented the TNT or many of the circuits although he is generally credited with developing the micronaut. As a technical writer myself (automotive) of some 24 years experience I never claimed or pretended to have invented everything I wrote about. I was a messenger. Some loved me some hated me. Usually people I grew up with found it hard and still do. Cest la vie. Not everyone can write tech in a manner that is easily understood. Some over complicate simple procedures to make it look harder then it is. Sometimes not realizing they are doing that. Some just blow smoke. The trick is to tell the story quickly in chronological order as simply as possible without leaving anything out. Because if you don't half your readers will not finish the article and your boss's (The publisher) advertisers will be upset and you will become a reader instead of a writer. BTW It is usually not a job you aspire to. You are usually conscripted. He must have had something going for him It is a tough business to say the least.

Lou,

I found my file copy of Dave Ingram's March 1989 article. The transmitter Ingram describes is a unity coupled "Double M". The untuned grid coil is wound inside the plate coil...ie. the grid coil wire is poked through the plate coil tubing. It is nothing like the ebay transmitter. Ingram credits "The Transmitter" magazine for the original and built two versions (with modifications) before he was satisfied, calling it the "Double M Special". (Ingram's writing style and use of exclamation points is a little grating but I can see how it would sell magazines.)

The ebay TNT transmitter looks like a copy of the "Single Control Low Power Transmitter" and straight from the early 30's ARRL Handbooks. Too bad it is built on ply board instead of a kitchen breadboard. Bill Orr is close. He added a cap across the B+ that doesn't show up on the ebay TNT or the Handbook.

Niel,

Yes. I took the print-out of that article sent by Garey to bed for a quick read. Glanced at the schematic and thought, TNT. Several paragraphs in I saw, Double M. Hmmm? Sounded familiar, but what does it have to with a TNT? With a few more paragraphs came the light.

The ebay TNT transmitter looks like a copy of the "Single Control Low Power Transmitter" and straight from the early 30's ARRL Handbooks. Yes again.

Too bad it is built on ply board instead of a kitchen breadboard. Would be easy enough to fix that tho. Yet, now that I have worked with REL rigs I understand that semi-gloss black painted plywood is "period". (Oops, quotation marks. :0))

Orr added a cap across the B+ that doesn't show up on the ebay TNT or the Handbook. OK Niel, I have to ask, what does that do for you?

73, Lou

While I love and use JB Weld for many applications, I wouldn't recommend it for this one. I've read it contains powdered steel* as a filler and will probably be quite lossy in an RF field.

*and I believe it from its color (that's colour for Lou!).

12567. Pwr Supply Xfmr Selection

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-02-10 22:17:47 UTC
From: Bill Stewart
Topic: 12567 Message: 12567

I have built numerous p/s for various one-tubers over the years. However, I have never really 'designed' one. Usually I'll find a xfmr that I think will give me the B+ I need, add the filtering, bleeder, etc and see what I have. More than likely, the B+ will not be what I want. Either it will be too high and I'll have to add dropping resistors to bring it down or it will be too low and will have to get a different xfmr. I ran across a p/s design
web site which the guy used upwards to 15 formulas to arrive at his final design. I'm looking a KISS method. The main thing I need is a good 'rule-of-thumb' for selecting the pwr xfmr voltage vs the target B+. For example, a one-tuber needs 350vdc at 40ma ...what xfmr voltage would be needed. Most of my needs would be 500vdc max.
Tnx, 73 de Bill K4JYS

Don,

Have you built any regulated supplies? If so, what method did you use.

I have a hefty xfrmr with multiple secondaries. I need well regulated B+ and screen supplies for an ARC5 transmitter.

From: mattgoff54@...
Topic: 12572 Message: 12572

I got a western electric model T-12 hand microphone a few days ago, because I have intentions of playing with modulation just for fun. It has the original cable and plug, which has me puzzled. Its smaller than the standard 1/4 phone jack and the plug is divided into four conductors, or so it seems there are 4 separate sections. Anyone have any insight as to what Im dealing with and if its at all useful? I imagine its a carbon mic, possibly a double button (think thats the correct terminology).

Also, unrelated and probably a past topic of discussion, but whats the word on finding beehive insulators these days? I have two white ones that were originally lead-ins but are the same otherwise. Id really like to get my hands on some of the brown or even blue varieties. Anyone know of a source or are they truly few and far between anymore?

73, Matt

I have not played much with regulated supplies. I hada gas tube regulated for awhile but when the reg tube died I let it die. I have strung neon bulbs or neon bulbs and resistrs for light regulation HOWEVER ARC5 power supplies I know a bit about. I have two ARC5 transmitters on the air. I did not find a need for regulation. Dave stinson recommendations on how to build one although perhaps not conventional actually work quite well. I have both stolen screen from plate supply through a resistor and powered them seperate. I have also used osc plate for screen . All three worked. If you are going to series cathode modulate then you need a more independant supply then just for CW. Hum is the big problem. It would be much less trouble if we ised 80 tube rectifiers I think but solid state rectifiers really make almost square waves and it is hard to knock the corners off so to speak. A low value ten watt wire wound on input 10 to 15 ohms helps a lo tand bypassing diodes also helps. Using multiple diodes on the string (so no diode runs anywhere near its max voltage rating seems to help. I run three typically in both side and usually build a doubler. BTW my No 19 supply will run my ARC5 stuff and visa versa. Similar voltage requirements. My Arc5s are modified for 12 volt service. A process requiring only a few minutes work and a dull headache figuring it out.
The best power supply I ever built was for my twin 811A linear. I got the design from the ARRL SSB handbook from the1970s. I did it exact (the power supply) and it is stone quite and works well. I have never built a better or as good a one. Why I dont keep that design for all is a good question. I do use a lot of what I learned. I looked a PSU schematics for many of the rigs I owned. Like my DX60B for instance. It has a very uncomplicated PSU design but works very well. I also looked at the PSU in my Kenwood hybrid TS830S. Not complicated either.
Bill asked a question. I count on 140 volts filtered DC from 120 Ac in . It is kinda my rule of thumb and that is under load . For instance all my doublers that work without a transformer from line voltage or those with back to back filament transformers (I dont do that anymore) net me under load believe it or not 282 volts. The same works for my No 19 supplies (I have two) using the ac output of the transformer. I don't use a flter choke anymore and very few commercial set do either. I read a piece by a former ham equipment designer on why he stopped using them and I understood what he said. They are a hum source with solidstate rectifiers. or can be and eliminating them has helped with that. I bypass everything with 01 caps and I used voltage dividers when I can rather then multiple windings. Back in the day we used to build linear hi voltage supplies using photoflash capacitors in series. I had built a couple fo them and they were quite. Power oscillators with directly heated tubes tend to hear too much so I just keep working till they get to a usuable state. Sometimes I am surprised at what fixes them.
I have a long way to go and am not yet satisfied with my progress but I have usable equipment so I am making progress.
Again though I would strongly suggest you read Dave Stinson's (ARC5 Group) recomendations on ARC5 AC power. I resisted for quite awhile but I am so close to his now I would be dishonest if I didn't give him credit. It just flat out works.

Hopefully it is a single button. Remove the element and hook a ohm meter to the element and speak into it. If it is a single button carbon the response will be excellant and wild. There are a half dozen good ways to modulate with it. Choose your poison. What some like others hate. Bottom line and the only one that matters is can you be heard and understood plainly and does you method of choice interest you. Usually you hate what you dont have. The rest is just smoke. I wont say my favourite but I have tried four methods. All worked. Some military mics have a small diameter plug. I usually rewire them for a three prong or if I don't need the PTT I just wire the element with a two contact 1/4 plug. It can be a real adventure.

Don,

I have read Dave's suggestions. I think I mistakenly thought he said regulated. Your reply has reminded me of Dave's comments. Thinking back, I believe he just recommends a good stout supply that does not sag on key down. Well that makes things easier.

Tnx,

Robert

I have notes I made. From the 550 dc in draw screen through a 20k resistor (I use 10 watts although he sqid 5watts.)from the same 550 line (which is your plate supply BTW) drop a 15k 10 watter and to the end of that a 100K to ground. (I use 10 watters but the 100k doesnt carry much load so that is overkill but "what could it heurt" At the uniion on the 15K and the 100 k take off your osc voltage. The seeing eye tube in you set does not affect operation. so can be removed especially since most of the crystal plug ins do not fit ham use anyway and can also be removed. If you run the osc at higher voltage and I have it just makes it harder to quiet down although the tube can stand it. I use a similar set up for my No 19. although screens and rx and osc all run with a nominal 270V supply. On transmit the voltage will sag even with the original dynamotor supply. You can build a 24 volt heater supply easily. (the heating industry uses 24 volt transformers everywhere) oryou can in a few minutes convert it to 12 volts by putting the heaters in parallel as they are seriesed. If you use original screen or plate modulation these voltages are fine. If you series cathode modulate it like I do then you need to add the voltage drop of the series modulating tube to your plate voltage so you have the 1625 finals at full spec for your sets plate voltage.(500 to 550) I use for that reason 750 , 200 for the ^Y^ and 550 for the 1625s. ALSO and this is a must. There is a white or off colour white capacitor at the front of the Pa tank coil. replace it right away before firing with a 1 to 2 KV cap (I use 01 2kv ceramic disc) It will fil very quickly in use if you dont and presents some phantom symptoms that will keep you guessing and wondering where did the power go? Since you know it is going to fail and the cure is under $2 just do it now and it will never happen. The roller inductor is more in the way then a help unless you are running to short an antenna. You could just put your own 2 turn llink around the cold end of the tank and be done with it or they will operate quite well with a low value high voltage cap in series with the antenna output and the roller at minimum setting. The relay if you go to 12v will need to be bypassed (I did that so the set is always restorable by removing the relay bypass wire.) And you might want a keying jack in the front which connects to the relay contact and case. (AKA Ground) Plugs for the sets are hard to find here so I fed my PSU wires through the plug socket holes and soldered them to the pin lugs inside . That way the set is easily and quickly returnable to stock and is not butchered. I usually use mine on AM with thw AWA Sunday events but for the Linc Cundall I event finished up the night with an hour to go with it on CW working Larry then Lou just before the bell rang for the day. Need any help just ask. I so remeber struggling my way through and how I got where I now am. Reaolly the ARC5s are a bargin. I paid $17 for both mine and bought them about a year apart. currently they go from between about $34 and $76 which isnt even the privce of the tubes in reality. donVe3LYX

Earler this past year I learned a lesson in testing from a UK Ham (Wales) that I would like to share if I may. He discovered I had an operational No 19 WS and he had an operational WS 52 (A receiver of the same era and of the type and application that would suggest they were used in concert during the Big One. In fact the knobs and dials are identical in design.) He asked if I was serious about trying a pond hop and I was. He laid out the procedure we would use and when I learned he had been a Marine Radio ops for a bit so I choose to listen. Since all he had Vintage operational at that time was a RX he would not be able to answer me with a vintage rig 9He has a T1154 but it wasnt at his QTH then) so didnt ask what I would say. He said I was to send every night at the same time on the same freq and if were were blocked go +5. And so We started. I sent very slow (it was a CW deal) figuring the very slow would stand out. We worked at it for two weeks minus a night or so when one of us couldn't be there. He choose what was 6 Pm here for me. A couple of times he told me he could hear some very slow Cw but wasn't sure. After about 7 or 8 days I told him thanks for trying but I figured it was a wash. He wouldn't let me quit and so I plodded on then one night he sent back to me by computer my message verbatim and said it was solid copy. There was no denyng it. I would have given up much earlier figuring it was hopeless. He knew better. The distance ATCF was 3725 miles and we were on 40M. We had set a time limit so I wouldn't be sending and sending . I usually sent for a solid 5 minutes using the CHU time signal to be on time with him. It was not a big inconvenience for either of us and worked out well. It was a method I learned that will help me the rest of my days. CW or AM. Conditions are not always good but I learned from him sometime they probably will be. Thank You Andrew.

Hey AWA Brothers,

I have a set of AERO Coils for 15-130 Meters. If someone plans on building a vintage SW receiver this might be what you need. It's excess to my current and future project list. I'd like to get $30 for the set plus shipping. I can only ship via USPS Priority Mail from home (53144 area code) and will charge the exact shipping cost to whomever buys this set. Figure it to be 2 lbs boxed which should run around $12 CONUS. Sorry to my Canadian (and other DX) friends, but Priority Mail above the north border is crazy and wouldn't be worth it unless you have a friendly address south of the border.

Here's a picture of the set: (I don't think they were ever used)

First come first served.

I'd like to get $30 for the set plus shipping. I can only ship via USPS Priority Mail from home (53144 area code) and will charge the exact shipping cost to whomever buys this set. Figure it to be 2 lbs boxed which should run around $12 CONUS. Sorry to my Canadian (and other DX) friends, but Priority Mail above the north border is crazy and wouldn't be worth it unless you have a friendly address south of the border.

Here's a picture of the set: (I don't think they were ever used)

First come first served.

I sent Dave, VE3NNG a porcelain knife switch a few months ago by USPS and it was just a small one. It still cost me about $11. So, shipping to Canada is still not cheap and does need to be taken into consideration. 73 – Mike

I see. Well as you will remember I just bought that uv199 from your pal. Sure it wasnt cheap but it wasnt crazy.
I have a brother and a sister who live south of the line. I used to ship to them and then go and get it as they were both by the border. I decided very quickly USPS was far cheaper. So it isnt cheap as you put it but do we quit because of that? Tis not the Canadian way. Persevere regardless. And since we dont pay for medical we have the spare cash.

Lou changed his mind on these guys, so they are still available.

I checked and it does appear they will send to Canada for around $16 or
so via First Class.

No, not like that at all. For example last year I had a hospital stay that cost over $30K and I did not have to pay anything. This past Wednesday I went to a clinic for blood-work, called my doctor’s office on Thursday and was in to see her the first thing Friday morning. Also all cost free. However, my premiums are sky high. – Mike

From: Roger Kuchera
Topic: 9796 Message: 12604

GM Gentlemen, I am in need of a procedure or instructions on how to put an RME Vernier back together. One thatI had was worn beyond use and I had to have a new main driveshaft machined for it. I guess I shouldhave taken more digi pix during disassembly.

I think it may have been described in an old edition of ER magazine.

Can anyone help?

Roger/K1TG

12605. Looking for a Meissner RX

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-02-14 16:52:55 UTC
From: Roger Kuchera
Topic: 12605 Message: 12605

Gentlemen, I am looking for a restorable Meissner Traffic Master/Scout receiver. I can trade for or buy theright receiver. A museum piece is not what I am looking for.

I have for trade the following:

Millen 90700, VariArm VFO (per Jan. 41 QST); several leaky paper caps were replaced; it works but the 2-wire resistor line cord went open. Complete with coupler. Could be used as a QRP TX with a healthy 2-Watts out.

Millen 90501, Frequency Standard; Replaced leaky caps and an open 30K resistor. The cabinet was bent (Straightened now) and extra holes were plugged with sheet Brass. It has been repainted (Black crackle).

Leonard! Communication is by definition: a process by which information is exchanged between individuals through a common system of symbols, signs, or behavior <the function of pheromones in insect communication>; also : exchange of information. You'll find no better place to share your knowledge and gain knowledge in exchange than this group. Although we do enjoy some "on air" events, a license is not a requisite for communicating with this group... only a desire to understand and enjoy the hobby.

Ron K3PID

I wonder if my Vibroplex has pheromones? Well it IS a bug..... sorry...

Ron, I'm thoroughly aware of the advantages of being a member of the group, even though I'm not really into transmitters. I have worked on radar a lot in the past but somehow never developed an interest in building or operating radio transmitters. The closest thing I have to a transmitter is a TBY-8, but it has never been fired up. I do enjoy reading Don's exploits with his one tubers, etc, but I don't think I'll ever get around to indulging in anything more than just listening.

Leonard! Communication is by definition: a process by which information is exchanged between individuals through a common system of symbols, signs, or behavior <the function of pheromones in insect communication>; also : exchange of information. You'll find no better place to share your knowledge and gain knowledge in exchange than this group. Although we do enjoy some "on air" events, a license is not a requisite for communicating with this group... only a desire to understand and enjoy the hobby.

Ron K3PID

I wonder if my Vibroplex has pheromones? Well it IS a bug..... sorry...

I'm not licensed, and since I have nothing to say I don't see the necessity of getting a license. I had a Halli HT32 once and thought about geting a license but there's too many rules & regs. So I'll just keep plodding along playing with my receivers and listening to others.

I'm building a two-27 Hartley based on WA9WFA and AB0CW's schematics. Both show the key, with a parallel cap, from cathode to ground. B+ will be ~250VDC. What is the approximate voltage across the key? Is it an improvement in keying, and/or safety, to put a resistor in series with that cap? If so, for some reasonable C and RC, R might be in the range of 100 ohms - 1K ohms, but what power rating? Thank you.

Cathode keying is quite normal in many older rigs. Some military keys are shielded but most hams know when the PSU is on don't put your fingers across any two points anywhere. Same goes for exposed wiring and coils. On my TNT I installed a Bunnel Railway relay (150 ohm or 6 volt) and key it. Not because I was afeared of the shock but because I don't like long lines coming from a self controlled power oscillator. It does nothing for stability. The relay allows me very short lines, less wobble when moving near it and low voltage keying. I was worried it wouldn't be fast enough but it can stay even with my Bug when keying. My homemade keys are wooden including the spring and so other then the connection nuts no shock hazard is available. They are faster then traditional keys as they never leave your fist no matter how fast you go. I played around with resistors and caps.Still use a cap(.01 1kv) but the resistor thing did not seem to suit the old style rigs.

From: mattgoff54@...
Topic: 12624 Message: 12624

I thought I would try putting together a TNT for 80m as per the classic handbook version, same layout etc. Its been giving me a variety of troubles. I have a list but if anyone could give me their wise opinion on these few Id appreciate it. First off, Im running a 210 and the tank is comprised of 12 turns copper and a 15 plate cardwell padded with a 100uf tan 1500v sangamo. All other caps are the old brown sangamos: plate blocking 500uf, grid 250uf, and 200uf filament bypass. Grid coil is wound on 1in dowel with magnet wire, 56 turns. Im running a fil voltage of 6.3vac because i dont have a good 7.5v source. The main problems Im having are bad tone, chirp, and some drift. I know, probably not unusual. My hartley with parallel 27's sounds like a million bucks compared to this though. When I tune through the range allowed by the smaller tank cap plate current goes from 15ma to about 55 as i open the plates. No real dip in between. Ive fooled with different turns in the grid coil to no avail, seems that more or less than what ive got shoots the plate current way up no matter where the tank cap is set. Im feeding it into 5 turns ant coil in into an mfg antenna tuner, set to where my icom tunes the freq i want. However with a tuning lamp on the grid end of the coil I never get the lamp all that dim, so I dont know of its really hitting resonance with the tnt. I thought the lamp was supposed to almost go out when the antenna tank is in resonance ans sucking the rf out. Could be wrong. Another observation is the tube....it has a visible blue edison effect on the outside of the plate even at the normal plate currents. Dont know if this means its gassy and might be part of my problem. Tone is a lot better with an 01a and substituted voltage values.

Any help appreciated. Sometimes I dont know how you guys build these things without going crazy, although I guess some would say we're all crazy hi hi. Thanks,

Matt

Krazy is a good thing!
First thing I would do and I remember the experience well is take a GDO and WITH THE TUBE IN PLACE test your grid coil for freq. It should be able to be pulled to your plate coil and tuning cap tank circuits freq so at some point should be on that freq. You will probably find it is nowhere near that. I suspect too low. That was the problem I had. Also, Lou just did some very interesting experiments yesterday exploring grid leak specs so we should let him give us the full report because it is very interesting what he found out. He is kinda Mr TNT. It was him that got me into this whole mess a few years back. Pulled me off the rocks so to speak.
In fact I was winding a grid coil for myself today. Plate coil is already done. I think I am addicted.

If cathode-keyed (grid circuit returned to ground) the voltage across the key will be limited to the cutoff voltage for the tube at 250V on the plate. For a a triode this will be approximately 250V divided by the amplification factor ("mu"), which for a '27 is 9, so we end up with about 28V.

If negative-lead keying is used - that's what you've got if the grid return is tied to the cathode at all times (even when unkeyed) - then the full plate supply voltage will be across the key.

> Is it an improvement in keying, and/or safety, to put a resistor in
> series with that cap?
>

If you are looking for safety, just opt for cathode keying over negative-lead keying. I don't think you'll get much current limiting with a resistor of reasonable value, because not only will the voltage-drop across the resistor increase the grid bias, put it will also subtract from the plate supply voltage; i.e., the effective plate voltage supply for the stage will be less by the voltage dropped across the resistor.

If you want to make a key-click filter with an RC circuit, I'd go higher on the C and smaller on the R for a given selection of time constant, for the above reasons. In other words, 100 ohms sounds more reasonable than 1000 ohms.

> If so, for some reasonable C and RC, R might be in the range of 100

Date: 2016-02-15 17:34:19 UTC
From: Ron Barlow
Topic: 12621 Message: 12628

Hi Dean, I key my 27 Hartley transmitter in the B+ lead (via a relay), so I can't readily determine the answer to your question, via actual measurement. However, looking at the curves for the 27 indicates that plate current cutoff occurs @ ~ 32 volts, with 250 volts on the plate. Thus, the voltage across the key will be in the neighborhood of 32 volts. This assumes that the grid return is connected to B-, not to the cathode of the 27 tube. lf the latter connection is used, the key up cathode voltage will be much higher".
I suggest that you do NOT add a resistor in series with the cap that you describe. That is an RF bypass cap. Adding such a resistor will reduce the ability of that cap to perform its function. The addition of such a resistor will also allow RF to appear on the leads to the key, which will likely yield some other undesired
results. 73 & GL with
your fb project! Ron

I was afraid this was going to get precise and scientific. I dont have a GDO and have never used one..I anticipated the grid coil being a bit of a pain so I started with more turns than I needed and started reducing one turn at a time until I had probably around 35 turns. That was coil number one. Now Ive done another one and have stopped at the 56 turns I have. I thought my problems were probably elsewhere but Im not sure. Im also unsure of the difference in inductance caused by using the same amount of turns of magnet wire (no idea what gauge, it came from a set of hair clippers. Radio shack really sucks these days) vs the small cotton covered wire, if there is any.

Grid leak resistor is a 10k 20 watt clarostat.

What's the winding length of your 32T and 56T coils along the form?

Put the 32T coil back in the rig and add a small 100pF variable across the coil. Tune the signal in on your receiver by adjusting the plate tank (cap), don't let the plate current get out of control, short dits until you find the signal. Then vary the grid variable... can you dip the plate current? If not a dip, is the current dropping towards fully meshed or fully open? This will give some hints which way to go for lack of a GDO. If you can dip the plate current, find the signal in your receiver or re-tune the plate tank to get it back on frequency. How's the note? Play with the grid capacitance around that dip and observe the note.

I tried a TNT once, worked ok, but modified it to a TPTG just to have a little finer control. My PP 45-45 TPTG has a 51.6 uH airdux grid coil tuned with a split variable (100pF / 100 pF). Takes about 25 pF (50pF / 50pF series) to get near resonance on 80M (which means there is about 13pF stray capacitance in the grid circuit).

Also, while doing preliminary adjustments, swing that antenna coupling coil out of the way and disconnect antenna lead(s). Get the rig settled before worrying about driving a load.

Hi Matt, First of all, I suggest that you absolutely not do any further testing until you increase the filament voltage to 7.5 volts, plus or minus 5%, as per manufacturers specs. To do otherwise will almost certainly result in tube damage. Aside from that, the low filament voltage will cause the transconductance (gain) of the tube to be lowered, affecting the performance in the circuit.

The 100 pf cap mica cap is very probably at least part of the cause of the frequency drift. Replace the mica cap with an air dielectric cap. My experiments with the use of solid dielectric caps in the tank circuits of my LC power oscillators always yielded drift problems. YMMV. The rough note is usually the result of oscillation on multiple frequencies--Due to excessive feedback, incorrect time constant in grid leak circuit (wrong RC ratio), etc. The incorrect feedback level can be the result of the grid circuit not being tuned correctly, in the case of a TNT or TPTG circuit. That 250 pf grid leak circuit capacitor may be a bit on the large (C) size. You might try reducing that cap to ~ 100 pf, if all else fails.

I suspect that omitting the tuner from the mix would simplify matters greatly. The tuner is adjusted to present a proper load at one specific frequency, while you are altering the transmitter frequency over a rather wide range, in an attempt to find the "sweet spot"---That's somewhat like a dog chasing its tail, IMHO. Use a resistive dummy load, until you have sorted things out. I like to use pilot lamps for at least part of the dummy load, as it gives me a quick visual indication of relative output power. Note, however, that the fluctuating resistance (from cold to hot) of an incandescent lamp load, will cause a chirp, in such a transmitter. If you have a suitable wattmeter, ignore the pilot lamp indicator suggestion--the wattmeter will tell the story.

When the plate current soars to 55 ma., it is an indication that oscillation has ceased. You would not want to allow this situation to continue for any significant length of time, as (depending on the plate voltage), the plate dissipation rating will be exceeded. That low filament voltage situation will be a particularly serious issue, under the high plate current situation, as the tube is the operating in an emission limited state--very bad news from all that I have read.

The blue glow is harmless if it appears on the surface of the glass envelope. Such a glow is only a problem if it appears in the space between the elements of the tube. The latter indicates excessive gas, and is more purple, in appearance, than blue, IIRC.

Above all, Matt, please correct that low filament voltage situation, before continuing---The life of your 210 depends on it! You could use a higher output voltage transformer (or 2 connected in series), plus a series dropping resistor, to correct that low filament voltage situation.

I have a list but if anyone could give me their wise opinion on these few Id appreciate it. First off, Im running a 210 and the tank is comprised of 12 turns copper and a 15 plate cardwell padded with a 100uf tan 1500v sangamo. All other caps are the old brown sangamos: plate blocking 500uf, grid 250uf, and 200uf filament bypass. Grid coil is wound on 1in dowel with magnet wire, 56 turns. Im running a fil voltage of 6.3vac because i dont have a good 7.5v source. The main problems Im having are bad tone, chirp, and some drift. I know, probably not unusual. My hartley with parallel 27's sounds like a million bucks compared to this though. When I tune through the range allowed by the smaller tank cap plate current goes from 15ma to about 55 as i open the plates. No real dip in between. Ive fooled with different turns in the grid coil to no avail, seems that more or less than what ive got shoots the plate current way up no matter where the tank cap is set. Im feeding it into 5 turns ant coil in into an mfg antenna tuner, set to where my icom tunes the freq i want. However with a tuning lamp on the grid end of the coil I never get the lamp all that dim, so I dont know of its really hitting resonance with the tnt. I thought the lamp was supposed to almost go out when the antenna tank is in resonance ans sucking the rf out. Could be wrong. Another observation is the tube....it has a visible blue edison effect on the outside of the plate even at the normal plate currents. Dont know if this means its gassy and might be part of my problem. Tone is a lot better with an 01a and substituted voltage values.

Any help appreciated. Sometimes I dont know how you guys build these things without going crazy, although I guess some would say we're all crazy hi hi. Thanks,

Matt

Subject: Re: [AWA Group] TNT Woes

Hi Matt,

First of all, I suggest that you absolutely not do any further testing until you increase the filament voltage to 7.5 volts, plus or minus 5%, as per manufacturers specs. To do otherwise will almost certainly result in tube damage. Aside from that, the low filament voltage will cause the transconductance (gain) of the tube to be lowered, affecting the performance in the circuit.

The 100 pf cap mica cap is very probably at least part of the cause of the frequency drift. Replace the mica cap with an air dielectric cap.

My experiments with the use of solid dielectric caps in the tank circuits of my LC power oscillators always yielded drift problems. YMMV.

The rough note is usually the result of oscillation on multiple frequencies--Due to excessive feedback, incorrect time constant in grid leak circuit (wrong RC ratio), etc.

The incorrect feedback level can be the result of the grid circuit not being tuned correctly, in the case of a TNT or TPTG circuit.

That 250 pf grid leak circuit capacitor may be a bit on the large (C) size. You might try reducing that cap to ~ 100 pf, if all else fails.

I suspect that omitting the tuner from the mix would simplify matters greatly. The tuner is adjusted to present a proper load at one specific frequency, while you are altering the transmitter frequency over a rather wide range, in an attempt to find the "sweet spot"---That's somewhat like a dog chasing its tail, IMHO.

Use a resistive dummy load, until you have sorted things out. I like to use pilot lamps for at least part of the dummy load, as it gives me a quick visual indication of relative output power. Note, however, that the fluctuating resistance (from cold to hot) of an incandescent lamp load, will cause a chirp, in such a transmitter. If you have a suitable wattmeter, ignore the pilot lamp indicator suggestion--the wattmeter will tell the story.

When the plate current soars to 55 ma., it is an indication that oscillation has ceased. You would not want to allow this situation to continue for any significant length of time, as (depending on the plate voltage), the plate dissipation rating will be exceeded.

That low filament voltage situation will be a particularly serious issue, under the high plate current situation, as the tube is the operating in an emission limited state--very bad news from all that I have read.

The blue glow is harmless if it appears on the surface of the glass envelope. Such a glow is only a problem if it appears in the space between the elements of the tube. The latter indicates excessive gas, and is more purple, in appearance, than blue, IIRC.

Above all, Matt, please correct that low filament voltage situation, before continuing---The life of your 210 depends on it! You could use a higher output voltage transformer (or 2 connected in series), plus a series dropping resistor, to correct that low filament voltage situation.

Ok I will try the suggestions and procedure Eric describes.. I had tried putting a cap across the grid coil but that stopped all oscillation..maybe too much coil for a cap. I'll also turn the thing off and rig up some 7.5v somehow.. I thought I could get away with 6.3 because the specs say 6-7.5 but I guess for this application I need all of it.

Cant really figure out the drift, Im pretty sure it still drifted without the padder cap. Which lead me to believe that it was due to plate dissipation. Without the padder it only tunes down to 3.550. Maybe ill get some copper strip and add another cap to the tank.

If you have an AC voltmeter handy, check the actual voltage from your "6.3" VAC supply while connected to the 210. Many transformers are wound for 115V... but actual line voltage in many places is higher. My 6.3VAC filament supply actually comes out at 7.2 VAC, within the 5% deviation. Also make sure you are using beefy wires from the filament supply if the run is over several feet, 1.25A filament current can result in a reasonable voltage drop if the wire resistance is too high.

It depends. If the glow is confined to the inside _/surface/_ of the glass, it is probably just elements in the glass fluorescing from electron bombardment. It is, in fact, an indication of a good, hard vacuum, and is probably a healthy tube. On the other hand, if the glow is between elements or otherwise inside the _/volume/_ of the envelope, it's probably gas.

Ok if you dont have a GDO make an Rf sniffer. A flashlight or Christmas tree bulb wih a one turn loop about the same diameter as your plate coi. Mount it on awooden stick and with the rig oscillating and key down bring it close to the plate coil. It will glow . if it doesnt turn the cap till it downs . if opening the tuning cap makes it glow more then you are high. Not enough turns. If closing makes it glow then too many turns. ideally a peak in glowing in the middle of tuning range is nice providing tuning range is where it should be . You 35Tis probably not too bad. I would this one at 34 based on past experience howevermany folks here run 10 tube in their rigs and some have TNTs if they used a 1 inch dowel their no of tuns would be good for you. If they used smaller or larger it would atleast give you a good idea. Above all. dont quit. A TNT is just a crystal oscillator without a crystal but a grid coil instead. Nothing more, nothing less. Despite the frustration you feel right now , a year or so from now you will be whipping them up in your sleep. And will look back on this with a knowing smile. You are getting good advice. BTW I like Blue glowing tubes. You can see what you are sending!. I have two here . A 45 and a 50c6. Beautiful. Worry not.

12648. Keying relays

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-02-16 01:38:10 UTC
From: JAMES HANLON
Topic: 12648 Message: 12648

This is a suggestion for avoiding a shock when keying a relay coil. The energy stored in the magnetic field of an energized relay coil needs to be dissipated somehow when the current to the coil is interrupted. If there is no other provision, the coil will build up enough voltage across itself to create an arc across some portion of its external circuit which will create a path for the current in the coil to continue to flow until the energy stored in the coil is dissipated in the resistance of the arc and the coil. That voltage can easily go up to several hundred volts, and it will very likely appear across your key. To avoid getting bitten, connect a silicon diode across the relay coil, oriented so that it is reverse biased when the coil is energized. The de-energized coil will develop a voltage which will turn the diode on, and current will flow through the diode and coil until the energy is dissipated in the coil resistance. Any ordinary rectifier diode from your junk box will do.

Or another good way to get there which I used and use now everyday is to take the 6.3 AC which is in simplistic terms an average and rectify it to DC (I used a bridge) the filter it with a large electrolytic . The result will be much closer (in spec tolerance) to the 7.5v you need. In my case and some might remember this I was making a AC supply for my number 19 WS and had a 600v 200ma , 5v, 6.3v new Hammond transformer. I joined the 5v and the 6.3 together giving me 11.3v but the set runs on 12 , actually 12.6v (paired 6.3 tubes) After rectification and using a generous electrolytic cap as a filter I have in operation just over the required 12.6 vdc.. Larry gave me a couple of tips on the last part of this setup that helped bring it right in the zone. (thanks) In this case I had to run DC because the meter needs DC (LT1scale) and the relay for rx tx needs DC.Otherwise I would have to have butchered this classic wartime radio and I didn't ant any SS parts inside it nor any hard wired mods. I have been using it quite awhile now with this set up. , In fact that is what is powering the set when I am talking in the recordings Larry made Sun evening. Anyway that will get U from 6.3 to the ball park 7 something voltage range easily. May even be a benafit. (filtered DC heater)
And BTW Still testing everyday every hour (top of the hour) I am here and awake with my Loop modded rat trap TX. So far I am talking to me.(fourth day) I also send in the middle CW (key is right there and I have it in my hand so why not.) Several have worked me on that set CW during the BK so I know it is getting out at least in CW. I would like to make sure it is working before this coming AM weekend. Have tested it for wobble and for field strength and I have about 3.5 watts out so it should be good but I need to make sure..It wont be strong but should be doable. Answers in any mode would be welcome. 3605 kcs or as near as possible.

Again, tuition and enjoyment. Soon I expect to retire, maybe within months. I will have to start selling to supplement my measly SS income then as I have nothing else. So, I will start selling on eBay. Guaranteed, everything I sell will be at a loss and in some cases significant ones. However, over the years, I bought items to enjoy, not to make money on. I have enjoyed them and continue to do so, and while I would like to get the max for everything I sell, it will not even be close to what I paid. But, like I said, I enjoyed them, learned from some, and that is what I spent my time and money on. 73 - Mike

Hi Matt, I can not say for certain that the use of a wirewound resistor in the grid leak assembly, will cause a problem, but be aware that the use of such a resistor may cause a problem. In general, conventional wirewound resistors are not suitable for RF circuitry. True, there would not be a large RF voltage gradient across the grid leak assembly, but there would be some. A carbon composition or film type resistor may be a more appropriate choice, at this location. You are correct regarding frequency drift being caused by excessive internal heating of the tube, Matt. But internal heating (caused by dielectric losses, etc.) in solid dielectric caps can also cause drift, due to a thermally induced shift in the dielectric constant. The RF current level in our high "C" power oscillator type transmitters, is quite large, thus the issue.

I don't recall a mention of the B+ voltage that you are using on your 210, but if you are using more than ~ 250 volts, it may be a good idea to reduce the B+ to this level, or less, until you have sorted out the problems. Tube damage would be less likely, and there are other good reasons for this precaution.

If you haven't read the W2SN notes, recently posted by W0VLZ, by all means, do so. I read these notes last eve, & found them to be very interesting and informative (Many thanks for posting them, Niel !). One of the problem areas that W2SN mentions, revolves around the use of a wood form for the grid coil.

You mentioned that the 210 failed to oscillate when you added an adjustable cap across the grid coil (which converts your TNT to a TPTG). I suspect that the minimum capacitance of the cap was large enough to shift the grid circuit resonant frequency downward, more than you may have expected. If that is the case, you could have restored operation by tuning the plate circuit to a lower frequency. You would have to remove some turns from the grid coil, in order to permit operation within the 80m band. A very good reason for retaining this added cap is that it would permit easier adjustment, of the grid circuit resonant circuit. Turning the capacitor shaft would be much more convenient than adding/removing turns from the grid coil. GL! & 73 de Ron n4gjv

You're right of course, Mike. If if included my time for the hours spent finding parts, restoring parts and building we would be well into four figures for a simple TNT. But I enjoyed the whole process and enjoyed operating the little rig. I'm glad I did it, though the day may come when I'm either forced to part with things or do so voluntarily as a means of affording something else I have always wanted to do.

I have been thinking seriously about augmenting my budget temporarily by selling off some of the other parts I collected while planning to build the receiver, PA stage, power supplies, etc. Although I think about building a project every winter, the fact (which I am just now finally accepting) is my lifestyle no longer supports that. To build something now would be more like a job (one more chore to get done) and there wouldn't be any enjoyment.

A very good reason for retaining this added cap is that it would permit easier adjustment, of the grid circuit resonant circuit. TPTG

But from experience, a TPTG is not a Kelley Contest rig! Swish swish swish across the CQ AWA AWA station while the Ip bends the DC I meter until you juggled that second Cardwell.

A TPTG does make a very FB sig tho...

Matt, the TNT is the '29 rig...

Whereas I generally agree with Ron's statements, a perusal of the 1930s Handbooks and QSTs will show many (most?) of the higher-powers rigs used wire-wound grid leak resistors. With large triodes, a fair amount of power needs to be dissipated in the grid leak, and unless you make up a large bank of carbon-comps*, it's tough to get a resistor with the power dissipation rating without using a wire-wound one. My PP-812 rig uses a wire-wound grid leak, and it has worked fine on 160M - 10M.

*and because of the bulk of this arrangement it may not be so RF-friendly either.

Ok thanks to all for the continued advice and guidance.

I have temporarily taken 7.5v from an old NRI tube tester using a spare four pin socket. Good idea, I dunno but it seems to work for now.

I did take the "rf sniffer" to the plate coil and tuned around. Bulb was brightest at full close of the cap, and dimmed as it opened. Plate current went up as the plates opened. So I took off turns, and repeated, etc. until now the bulb seems to be dim at close, gets bright as it hits 3.550, and begins to dim again beyond the 80m range. Plate current stays tame throughout. The tone is still rather rough. Sounds like two pitches alternating between each other very quickly. Or perhaps like an alien spacecraft of some kind. And Im using a heath regulated PS. I might try to upload an mp3 of what I hear on my icom, but the wave looks a lot better than when I started. I think I'll try to take more off and if I go too far Ill try the variable in the grid circuit as Eric suggests.

Resistors... I'll try subbing in a carbon dogbone and see what that does. My hartley has a carbon but thats also two 27's.

I wouldn't monkey with it. Sounds like you have it bang on. I am not a fan of TPTG and I have two. Pain in the butt to run compared to the TNT. You also have to know that monitoring a rig in the same house doesnt always tell the tail. Everything is overdriven. I would try dropping the plate voltage a bit and if that didnt work try a different value of gid leak cap. If your gridleak resistor goes to the cathode or B neg directly there is no harm in using a wirewound. Some old circuits used a resistor and a choke. kinda almost similar. If it goes to the coil parallel to the GL cap perhaps not the best. That said my 211 hartley has a big ole ugly wirewound for its grid leak. I dont think a carbon could stand it. Maybe several in parallel could. I am impressed with your use of the sniffer. Wonderful tool with many applications. Unlike meters etc it never lies.
Keep at it and GL. You are making progress at a breakneck speed. most impressive.

Thanks fpr the encouragement Don. And yes I think you were right, should have left it alone. But now I know that it was 38 turns at its best. I also think most of my tough tone issue is related to the AC on the filament. Im using two 47 ohm 2 watt carbons to key it, but it sounds a lot better with an 01A and 5v from the 1A iPhone charger supply. Not perfectly clean but mich better. I switched out the plate blocking cap from a 500pf to 200pf, which was one of my fil bypass. I thought the blocking value might be more critical than bypass so I put .01uf in as bypass caps. I'll have to play with the grid leak cap and resistor tomorrow.

Yes hopefully that will be the case. Although I feel like using DC is cheating? Is that a common practice? Maybe the resistors arent EXACTLY the same and thus some fluctuation.

Im just trying to soak up all the knowledge I can. The old 20s stuff really fascinates me. My dad had a few old philcos and such and as a kid I fooled with them, but I drooled over the atwater kents I saw at the antique flea markets. I do like to work cw for the pleasure of working cw, but right now getting a signal out a few hundred miles from a few globe triodes is way more satisfying than working dx on a 756proiii.

I live in Morgantown, WV which is about 80 miles south of Pittsburgh, PA. We are probably 400 miles apart. I imagine thats not too far for a few watts if conditions arent bad.

If the resistors aren't the same you would get 60 Hz modulation of the carrier. But you can get the same thing from other causes - RF getting back into the power supply is the most common. One way to rule it out is instead of using a pair of resistors, use a pot rated for the power dissipation and use the wiper as your C.T.; see if you can adjust for no (or at least minimum) 60 Hz modulation.

From: Niel - W0VLZ
Topic: 12678 Message: 12678

The reverse beacon network is at http://www.reversebeacon.net/ . Lots of times during warm weather I take my KX3 to the park. Using the RBN I can tell whether the band is dead or people just aren't listening. All I have to do is call "CQ" or "test" and any reverse beacon stations hearing me automatically posts my call, frequency and signal strength to the web. It will work for your TNT if it is stable enough. I usually look for signal strengths in the teens before I think I might have some QSOs.

Sub your own call for "w0vlz" in the link below then call "cq" or "test" in the CW band of choice.

Once in awhile I get a register on the RBN but not often. I operate everyday. I check CHU time signal. And WWV. If I can hear them i know that band os pen and can how good it is. Sometimes in evenings I check W1AW code practice which is just a bit below my usual spot and quick. I can tell how strong the band is by how good they sound. It has been very helpful to me using it. Yes in good conditions we should be able to work. Anytime you want to try just give me heads up and I will listen.

12680. ARS buss wire

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-02-17 19:47:12 UTC
From: Louis Vermond
Topic: 12680 Message: 12680
Attachments: 1 described; binary payloads are missing from this source WARC

Hello,

Recently Jon, AB9ZG, and I had a conversation about the Antique Radio Supply offered buss wire. (www.tubesandmore.com/products/S-W140) The title says it's #12, but the dimension shown is for 14 gauge (0.064"). Whatever the case, it has always looked both too large for #14 (which I want) and with tinning too shiny... too"new".

Jon had ARS buss and offered to solve the #12 / #14 size mystery. His full report can be read below.

I brought in the ARS buss and worked it a Jon did. The results were threefold and all positive.

1. The drawing reduces the gauge so it looked closer to my idea of what #14 should look like.

2. The sheen of the plating became somewhat muted.

3. Best of all, the very soft original wire became tempered / springy as buss was and needs to be.

73, Lou
VE3AWA

The initial thickness of the buss wire was 0.064" - the same as the diameter of 14 gauge wire.

So the cross-sectional area is 0.004096 sq. in. This is less than 12 gauge wire at 0.005128 sq. in. So even initially, the wire is substantially undersized.

Next the wire was stretched by approximately 27%. There is no special significance to this particular amount of elongation. I simply tugged on the wire hard enough
to straighten it out and then some.

The final thickness was 0.057", so the cross-sectional area was 0.003249 sq. in. This is nearly the same as 14 gauge wire at 0.003227 sq. in.

Now work-hardening copper won't make it stiffer, strictly speaking. It will however increase the yield strength which makes it springy and not so apt to bend permanently.

In this case, elongating the wire by 27% increased the yield strength by a factor of greater than 2.

I believe the wire is probably #12 since you have to measure it diagonally to get equivalent diameter as only the corners would touch the circle if you drew one around it. 73 - Mike

Subject: [AWA Group] ARS buss wire

Hello,

Recently Jon, AB9ZG, and I had a conversation about the Antique Radio Supply offered buss wire. (www.tubesandmore.com/products/S-W140) The title says it's #12, but the dimension shown is for 14 gauge (0.064"). Whatever the case, it has always looked both too large for #14 (which I want) and with tinning too shiny... too"new".

Jon had ARS buss and offered to solve the #12 / #14 size mystery. His full report can be read below.

I brought in the ARS buss and worked it a Jon did. The results were threefold and all positive.

1. The drawing reduces the gauge so it looked closer to my idea of what #14 should look like.

2. The sheen of the plating became somewhat muted.

3. Best of all, the very soft original wire became tempered / springy as buss was and needs to be.

73, Lou

VE3AWA

The initial thickness of the buss wire was 0.064" - the same as the diameter of 14 gauge wire.

So the cross-sectional area is 0.004096 sq. in. This is less than 12 gauge wire at 0.005128 sq. in. So even initially, the wire is substantially

I'll have to look into the RBN, not really sure how it works. A few months ago I was putting a johnson adventurer on the air and I read that the first even harmonic with an 80m rock was going to be bad..but how bad... So I was forced to open a laptop and I found a site called Global Tuners, which is a collection of remote controlled multi mode SW receivers in various locations, US and overseas. Streaming audio with about a 4 second delay. But it told me my 7kc harmonic was indeed pretty healthy in Indiana and Buffalo, NY. I havent been too concerned about band conditions because Ive been inactive for 5 years. Have to get a feel for it again.

Callsign here is KC8ZQS and Don, Ill take you up on that. Ill give a shout here before I put it on for some tests.

Assuming you get square cross-section wire by squeezing round cross-section wire into a squae shape, ie., the cross sectional area of both wires is the same, then measure the length of any side of the square wire to find the equivalent round wire diameter as follows:

Assume S = length of any side of the square wire, D = diameter of round wire

Then D = 2 x S / sqr root of pi

I think. Mike, W6MAB

I have used Glob Tunrs also. Re our distance. I checked it out. We are 340.5 miles apart ATCF which is comfortable on most good nights. So anytime. As long as I am home, and that goes for anyone else wanting to proof something too.
Inspired by some pictures I got from lou and your adventures I have been building another TNT. I have most of it done but the power connector and am still wondering where to steal a variable cap from, that is period correct.
I couldn't find a 10 tube and only have one decent working 45 so I built it for a 211 as I had a good ceramic socket as well. 80M, this one. I can use my 211 Hartley supply. I borrowed its tube too but will get another. I am saving my pocket change as we speak. They are about 90 to 100 bucks here. Overnite delivery.

Hello,

My first TNT (now 42 years old) has always had a somewhat raspy (not RAC) signal tone. Inspired by the current run of TNT Woe postings, I finally look into what could be the cause of that T.

The rigs filament centre taped 75 ohm (measured 76.1 ohms) Pilot resister seemed a good place to start.

1. Pilot resister measured from c.t. to outside terminals: 36 - c.t.- 40.2 ohms.

2. Separate centre tapped 7.5 V filament transformer measuring 3.88V each side of centre.

Wiring from the schematic below and operating the rig under worst case conditions (hard loaded into a swinging open ladder line fed antenna) the signal quality changed from a definite trace of modulation (T-6) to a near perfect tone with slight trace of modulation (T 8).

In one of the ARRL TNT articles the author mentioned that while a c.t. filament voltage source would be best, a untapped filament supply would do if a c.t. resister was used. In this case, the first choice was correct.

Tomorrow... Converting the TNT to D.C. filament voltage operation. Spoiler: T9

I run several of mine with two 22 ohm resistors across the filament and fed in the middle. On light duty stuff (BK style) 2 watt resistors work fine.For really heavy work like my twin 811A linear , and I mention it because they are directly heated triodes so it is very relevant, I used several 2 watt 100 ohms carbon resistors on parallel to get the same values. I used to use wirewounds but would have occasional phantom failures so this has been a total cure. At BK power levels it would not be an issue. I run most sets now at AC heater and have gotten the RAC down to a managable level. Sometimes an almost pure note. I bypass everything with 01 caps in my power supplies. I do use Dc filament supplys for regens. Then you actually have a real receiver. Makes your very best rx look deaf. Also I have discovered much of the noise comes in through the powerlines. Could be the neighbours welder , or his 60cycle carrier house/ garage intercom. or the rotting ancient transformer across the road but it varies greatly. My indirect heated filamnet rigs like the 6sl7/6v6 regen/ transmitter transceiver I often run on a portable vibrator supply made from a old 6 volt ford car radio. It works very well. Because the grd is common to both filament 6 volt and the B-neg suppy it does not work with my cathode keyed direct heated BK style rigs. I would have to B+ key them but cannot bring myself to do that.
My monster hartley is a bit raspy. It is however side fed without the aforementioned resistor network. Perhaps I will put a resistor network on the new 211 TNT.
For six volt Dc I use a pair of sealed 6 volt rechargable lantern batteries charged from a 12V solar panel. The joint where they are connected in series gives me two 6 volt sources that are ALWAYS charged and ready to go. (plus 12v Dc if I need it.) I tried using small 140 watt 12v to 110 inverters to supply B+ after recification and dobling but they are RF noisy.
it is interesting to note that No linear that I know off uses DC heater and the traditional tubes are all directly heated triodes. That is what got me thinking down this path. That said there is no question in my mind that DC heaters are the ultimate deal. I see many run regulated B+ supplies. Would be nice . here all B supplies are homebrew. The tripler (211A Hartley power) being my personal favourite.

Update: put the pot on the fil as Larry suggested and I could easily hear where the center is. But it was still a little rough sounding. Out of curiosity I put it to my homebrew type 80 rectified PS, which is now usable thanks to some of you. Its comprised of a Thordarson 350-0-350 @ 70mA, an 8 henry 300mA choke, and two 7.5uf 1400v Aerovox cans (new production from ebay). And the tone is far, far better with this PS. Go figure. I guess Ill be tearing into the heath supply and maybe replacing caps.

Now if I can get rid of the padder cap and its accompanying drift I'll be almost good to go.

I have to agree with Steve. From here in central Maine I routinely work VE7s on the west coast of Canada during the BK event on 40 and 80 meters. 160 meters is a little hit or miss - propagation has to be reasonably good for that at BK power levels.

Hi Larry et all, I can't be absolutely certain, without seeing the schematic diagrams, but I believe that the wire-wound grid leak resistors involved, in the 30s vintage QRO rigs, that you mention, are isolated from the RF signal---. Either by an RFC, a bypass capacitor----Or the grid leak resistor is connected to the center tap of a balanced tank circuit. In all of these cases, only the DC grid current would actually be flowing through the wire-wound resistor. (Only a meager trace of RF current flow should be flowing through the grid leak resistor, if the RFC, or the bypass cap is performing its intended task correctly-----or that the center tap of the balanced tank circuit is accurately connected to the RF node, of the tank coil). Note that this typically applies to PA, IPA, and frequency multiplier stages. However, in the case of the grid leak assembly, that is typically used in our power oscillators, the grid leak resistor is connected in parallel with its associated capacitor, and is located directly in the RF signal path. Again, I realize that there isn't a great deal of RF voltage appearing across the grid leak, but there is some. Personally, I don't have a warm, fuzzy feeling abut putting a wire-wound resistor (essentially a very low Q inductor, shunted by a very low Q cap---the capacitance due to the inter-winding parasitic capacitance between the turns of resistance wire) in the signal path. Anyway, that's the root of my probably tainted line of reasoning. I personally would not use a wire-wound resistor, in that location, in my rig. (Nor would I have good reason to do so, due to its low power level !). FWIW, my original purpose for mentioning this issue, was to provide a very last ditch desperation type effort, in case nothing else provided a cure, for
the problem. 73 de ron

> I can not say for certain that the use of a wirewound resistor in the grid leak assembly, will cause a problem, but be aware that the use of such a resistor may cause a problem. In general, conventional wirewound resistors are not suitable for RF circuitry.

Whereas I generally agree with Ron's statements, a perusal of the 1930s Handbooks and QSTs will show many (most?) of the higher-powers rigs used wire-wound grid leak resistors. With large triodes, a fair amount of power needs to be dissipated in the grid leak, and unless you make up a large bank of carbon-comps*, it's tough to get a resistor with the power dissipation rating without using a wire-wound one. My PP-812 rig uses a wire-wound grid leak, and it has worked fine on 160M - 10M.

*and because of the bulk of this arrangement it may not be so RF-friendly either.

I think W0VLZ is the farthest I have heard west of me. And then we got stomped by QRM right on top of us. I would like to hear a VE7 here. Next time you fire up on the west coast give us a heads up and I will listen on freq. Probably in truth I never gave the possibility a serious thought.
BTW Isnt the AWA AM QSO party this weekend? I have been working on my arsenal and have several ready to go including a 45 tube Hartley series cathode modulated with a 01A. Just popped my best 45 in it last evening. I have two weak ones but one almost new that is very strong comparatively speaking. Also found a good way to adjust modulation depth to keep the possibility of FM to a bare minimum if at all. Using the BFO function on my digital rx with the step set very narrow and trying to modulate with out an audio note change(hetrodyne note) Since an audio note change would only be a few cycles (20hz) it is very easy to detect. First find out where it does it then back off just till it doesn't. Will probably fire up the ARC5s and the No 19 for the event. The Dx60B station is now gathering dust and is for sale. Too new for my taste even though it works pretty good.

5 over S9 hr. Fair amount of chirp, but tone sounds nearly DC. There were also some frequency excursions both up and down, not really consistent drift, more erratic. Frequency would be stable for a while then suddenly start moving up or down, then stabilize again for a while.

Well that is certainly fun. Of course you can cathode modulate your ARC 5 which is what I do through your CW key connection without the relay. And it works on TNTs and Hartleys as well.
The Loop is fascinating.
Take your best RX and put it on Cw , Listen for your TNts hetrodyne. Place the loop close enough to modulate but far enough away the note (Hetrodyne) stays the same note (Musically). That will give the best performance technically.(absolute minimum signal walking) In reality I might push it a bit but not much.
I unfortunately have to play(fiddle) tonite from 6 to 8 pm so will miss the opening of the QSO party but I aim to be home as soon as I can and on air. Probably 9 pm for sure if not before. I want to use the cathode modded hartely for at least one contact, The 45 Loop modded hartley for another both on 80m and will try and stay above 3800 so I can play with all. Then I want to to one with the40M loop TNT which has been my best (and first.) After that the Arc 5 on 80M and then my No 19 WS. I am hoping to run all weekend barefoot and to leave the DX60B station off.
BTW I have listened to your recording about a dozen times. Sounds really good here.
If you are playing in the shack give me a heads up and I will listen for you. Any mode.

Topic: 12624 Message: 12729

>The rough note is usually the result of oscillation on multiple frequencies--Due to excessive feedback, incorrect time constant in grid leak circuit (wrong RC ratio), etc. That 250 pf grid leak circuit capacitor may be a bit on the large (C) size. You might try reducing that cap to ~ 100 pf, if all else fails.

Ron mentioned the time constant of the RC grid leak combo. While building my Hull Hartley, I came across a couple references on this subject. In Army Manual TM-11-665 “CW and AM Radio Transmitters and Receivers”, on page 47 it says the RC time constant “should be large compared to the period of oscillation, but not too large.” I interpreted that practically to mean; at least do not use an RC time constant that is below the period of oscillation. The manual does not quantify what “too large” means.

The period of oscillation at some target frequencies is:

1.8MHz = 0.555uS

3.5 MHz = 0.286uS

7.0 MHz = 0.142uS

The time constant is R(ohms) x C(Farads).

In my case, a 5000 ohm grid resistor required the following minimum capacitor value to keep the time constant at or above the period of oscillation, according to the manual:

1.8MHz = 111pF

3.5 MHz = 72pF

7.0 MHz = 28pF

The manual further indicates that the RC time constant should be such that it “fires” as peak plate voltage is reached. If the RC fires too soon (TC < period of osc.) the waveform will be distorted. The grid capacitor must hold enough charge to keep the grid negative for at least one cycle (TC >= period of osc.). The grid capacitor must be large enough C to have a low reactance compared to the grid resistor, and also must be at least five to ten times the grid-cathode capacity of the tube.

Frederick Terman (Radio Engineering Handbook) says the grid condenser capacity should be greater than the grid-cathode capacity, and large enough to have a low reactance at the operating frequency, but not so large as to cause intermittent operation.

With that information, I tried 100, 150, 200, and 250pF capacitors with a 5000 ohm resistor. My notes indicate that 250pF is too large for 40m, so I parallel a 4700 resistor to lower the total R. I reasoned that 250pF and 5000pF was thus “too large” in my case. The other effect is a lower grid bias on 40m because of the lower R. Ideally, we could optimize the RC combos for each band and have separate plug-in RC pairs – if one was that interested.

Had a good time in the AM QSO party tonite. Came in late, worked a bit below the group but them heard Larry with the Flagship call and really wanted that in the log so jumped in. Had a great time both operating and reading the mail till just few minutes ago. Nice to hear Mike FS and John BE. I recognized John's call immediately but couldn't figure out why. He knew. He was my first contact in the BK. Some of the others I know sort of . I was running the No 19 set (currently about 16 watts out) They have a very unusual form of grid modulation. I could hear everyone although when I signed it was getting a bit rough. I stayed reading the mail and it got better after a bit. I laughed right out loud when the 3rd Don KYZ asked if I was modulating a self controlled osc. I said to myself. "You wouldn't need to ask twice" There was one sitting all hooked up on the bench in front of me. He is lucky I had signed ;>) Conditions were not good enough to use it anyway. It wasn't rough but not super conditions which is what you need for only few of watts. Anyway , real nice time. Is Tim HRX flagship call, Tim Walker ?

Good and interesting information, Steve. I realize that a ridiculously large RC would probably be bad, but didn't (and still don't) understand all the reasons. One obvious one is that it is difficult to manufacture a large C without an increase in the R and L parasitic elements. I wonder why too large a C would cause "intermittent operation." The grid-leak R is set by the grid leak bias and grid current that the tube wants to "see," of course.

I am going to go on now from about 8:15 to 9 am . If I can find a quiet hole around 3840 or up in 10 kcs I would like to try the cathode mod hartley. This afternoon I am hoping to put the 80M ARC5 on for the AWA net. I might have to get Dave (- - 2 J) to relay me in as he usually can hear it.
You did a nice job last night Larry.
Lou is probably saving himself for a big finish. I was hoping to hear him as well.
We gotta get Mike to drag up some of his basement treasures and fire them up.
Always neat though to put a voice to a name. Good to hear him on. And Three Dons ! KYZ, GGL and LYX. That won't happen again soon. I guess I was lowest power (18W)with John BE (32W) next. I could hear everyone. Even the Florida guy at the end although just.

This is really good information Steve. Wonder how critical it is since people do change bands without changing the C in the grid. Also, one TC is usually considered to be 63% (this is (1-e^-1) for 1 TC) of RxC. Also you mentioned raising the C, which would increase the TC and increase the period. That of course would have the effect of lowering the frequency. Thanks for digging out this information. 73 – Mike

Subject: RE: [AWA Group] TNT Woes

>The rough note is usually the result of oscillation on multiple frequencies--Due to excessive feedback, incorrect time constant in grid leak circuit (wrong RC ratio), etc. That 250 pf grid leak circuit capacitor may be a bit on the large (C) size. You might try reducing that cap to ~ 100 pf, if all else fails.

Ron mentioned the time constant of the RC grid leak combo. While building my Hull Hartley, I came across a couple references on this subject. In Army Manual TM-11-665 “CW and AM Radio Transmitters and Receivers”, on page 47 it says the RC time constant “should be large compared to the period of oscillation, but not too large.” I interpreted that practically to mean; at least do not use an RC time constant that is below the period of oscillation. The manual does not quantify what “too large” means.

The period of oscillation at some target frequencies is:

1.8MHz = 0.555uS

3.5 MHz = 0.286uS

7.0 MHz = 0.142uS

The time constant is R(ohms) x C(Farads).

In my case, a 5000 ohm grid resistor required the following minimum capacitor value to keep the time constant at or above the period of oscillation, according to the manual:

1.8MHz = 111pF

3.5 MHz = 72pF

7.0 MHz = 28pF

The manual further indicates that the RC time constant should be such that it “fires” as peak plate voltage is reached. If the RC fires too soon (TC < period of osc.) the waveform will be distorted. The grid capacitor must hold enough charge to keep the grid negative for at least one cycle (TC >= period of osc.). The grid capacitor must be large enough C to have a low reactance compared to the grid resistor, and also must be at least five to ten times the grid-cathode capacity of the tube.

Frederick Terman (Radio Engineering Handbook) says the grid condenser capacity should be greater than the grid-cathode capacity, and large enough to have a low reactance at the operating frequency, but not so large as to cause intermittent operation.

With that information, I tried 100, 150, 200, and 250pF capacitors with a 5000 ohm resistor. My notes indicate that 250pF is too large for 40m, so I parallel a 4700 resistor to lower the total R. I reasoned that 250pF and 5000pF was thus “too large” in my case. The other effect is a lower grid bias on 40m because of the lower R. Ideally, we could optimize the RC combos for each band and have separate plug-in RC pairs – if one was that interested.

Had a good time in the AM QSO party tonite. Came in late, worked a bit below the group but them heard Larry with the Flagship call and really wanted that in the log so jumped in. Had a great time both operating and reading the mail till just few minutes ago. Nice to hear Mike FS and John BE. I recognized John's call immediately but couldn't figure out why. He knew. He was my first contact in the BK. Some of the others I know sort of . I was running the No 19 set (currently about 16 watts out) They have a very unusual form of grid modulation. I could hear everyone although when I signed it was getting a bit rough. I stayed reading the mail and it got better after a bit. I laughed right out loud when the 3rd Don KYZ asked if I was modulating a self controlled osc. I said to myself. "You wouldn't need to ask twice" There was one sitting all hooked up on the bench in front of me. He is lucky I had signed ;>) Conditions were not good enough to use it anyway. It wasn't rough but not super conditions which is what you need for only few of watts. Anyway , real nice time. Is Tim HRX flagship call, Tim Walker ?

Yep! W1GIG "under normal circumstances."

Good talking with you last night, Don. Glad you had fun. It was also good to hear Mike N4FS on. I didn't hear Lou, but that doesn't mean he wasn't trying.

I hung it up around 11:20 EST. As Mike said, it was "way past my bedtime."

I'll be on this morning for a bit. I'll check into the AM carrier net on 3835 KHz at 8:30, and I'll be running the Sunday PM AM net on 3837 KHz at 4PM.

73 and thanks for participating,

>raising the C, which would increase the TC and increase the period.

Yes – but of course we'd ordinarily treat the period of oscillation as a design constant since it is just the inverse of the operating frequency: 1/f (Hz). That is, if we presume the RC combo is being optimized for a given frequency.

>Wonder how critical it is since people do change bands without changing the C in the grid.

Ripe for experimentation Mike. Anyone?

We all do some degree of qualitative evaluation of our rigs' signal (growly, raspy, chirpy, etc.). You could simply vary the C values to see what sounds best.

If you want to get down in the weeds with it, you could try a SPICE analysis I suppose. That may at least characterize the sensitivity of the C value while holding all other variables constant. Empirical testing on an actual Hartley would require some way to characterize the variables such as loading, coupling, feedback so they may be treated as constants as grid C is varied. Then you'd have to select some figure of merit for signal purity and a way to measure it. Who's got the time?

I no longer have any simulation/modeling software, so cannot do a SPICE. Yes, frequency is the reciprocal of the TC and that is why I said frequency would decrease with an increase in C. One of these years I'll play with it and derive some empirical results, if I ever get around to it, HI. 73 – Mike

Yeah - old buzzard transmissions have been happening ever since the
beginning of 'fone on amateur radio, maybe longer. For some that's the
only kind of transmission they know how to make. Don's a good guy,
though. I usually like the other station(s) to buzzard on - it lets me
get some work done at the bench!

I'm glad a stayed in for a bit longer - logged another 4 stations after
Don KYV checked in. One of them was you.

Oh , Alex, Sorry I was away when the post came up. Just got home. I was on earlier with the group and last night as well Just submitted my log. Thanks Mike for stepping in and giving Alex the hinweiss.
I used the No 19 in the whole weekend. It was doing a serviceable job for me and I am enjoying it a lot. If you didn't get in with the group in time, anytime you want to try I will go on with you. Just tell me when and where. 3605 is a good place for us with our Canadian license as it is a quiet spot and we are allowed there. On 40M I used to do testing with VE6PG on 7120 for the same reason. If busy go up 10kcs.
Here is a photo the XYL took during this afternoon's adventure.
BTW Mike who answered you has one (No19) as well or did. I think he still has it if I understood correctly.

Didnt get to do the qso party as I had to get a transmission back in my truck. I looked for the AM carrier net and any activity and didnt hear anything. Probably not at the right place at the right time. Hopefully next time.

Lots of good grid leak info there Steve and all who replied. I'll have to digest all of it. I dont have many caps and appropriate wattage resisitors so my options are limited but I'll play with it some.

I made two QSO's with the TNT last night. I found that the drift I had was largely due to the choke I was using in the B+. It was a large receiver choke, not sure of the inductance but switching to a smaller choke (actually the in from my 27 hartley) helped the drift significantly. It also brought the frequency up, so that my 17 plate cardwell bottomed out at 3.607. Solid padder caps all drifted, so now the cardwell wears a pilot midget condenser on its back. The rig still drifts slightly. Maybe 200 Hz in the 45 min I was operating. Been investigating..maybe the choke still isnt ideal for 300-400v.

Does anyone have a good source for the little center tapped fil resistors? Im still using a 500 ohm pot, and while I can get it sounding nice with the pot, If I use two resistors, carefully chosen to match each other, its noticeably not as clean. A small adjustable tap wirewound would be ideal.

A few days back Lou was fooling around with a 203 tube and his TNT. I have a 211 Hartley but never thought about a big tube TNT. And then we had Lou's on air Phone test. and then Matt Goff's TNT adventures. well a man can only take so much so I varnished a board,dug through my junk box and here it is. I am calling it Louis II since it is my second TNT and Lou also inspired the first one. It is a wired and proofed. GDO says the main tuning centre is the 40M band and the grid coil peaks at 7050 to 7150 on the GDO tube installed. I have to do the power cabling to the PSU or unhook the Hartley's. This is my 211 from the Hartley but I would like to pick up another so I have a pill jar collecting $ and pocket change. I haven't put power to it yet but I always have to work through that in my mind first and double check everything. And I have to decide on Antenna coupling although my other TNT system works so well I may just duplicate it.

Hello,

As some here know, I built a P-P TPTG rig some years ago. While this circuit has lived up to its reputation for good stability and tone, with two controls plus hand effect it is not a "Kelley contest rig".

Recently I acquired a pair of vernier drive 500 mmfd. Cardwells which I have temporarily installed in the rig. While they have helped with zeroing in on frequency, tank condenser hand effect is still an issue.

As you see below, I have installed an wood dowel extender which does away with this problem. While the extender does the job, wood lacks the pizzazz of Bakelite or hard rubber.

Does anyone here have a metal lathe able to make* an extender for me? I will provide a drawing and a length of 3/8" dia. hard rubber rod.

Payment/trades discussed directly.

What say?

73, Lou
VE3AWA
Ldvermond@...

* It involves: Cutting to length, internal 8-32 threaded hole each end and 6/32 taped set screw holes each end.

The grid circuit is unaffected by hand capacity.

It is neat. I have been watching it for over a week since the guy took it of eBay the first time claiming an error in the listing. I did get it, but for a ridiculous amount for a one tube set. 73 - Mike

Congrats, Mike. For that Unusual BC Set, not ridiculous at all. Wonder if it tunes up to 1800? Lou

Matt,
On the 211 Hartley I run just around 400 volts key down. (44watts) The tube can handle 1000v. I am just not comfy there. The PSU I built which also does the keying is a AC/DC voltage tripler with a 10volt transformer for the heater. It doesn't work too bad surprisingly. (just read a piece on that style by James Millen , Sept QST 1938, pg 63) I used it for all 40M work in the Linc Cundall and it usually gets an answer if I use it for regular work, almost everytime. So since it is the same tube I think I will just unhook the Hartley and hook up the TNT. I ordered the other 211 this morning. $75 in US funds. I know I could get a lot more power from it but I am simply not comfortable with that. I live in a vintage rig vacuum. Most local hams say "TUBES?" or "Code???" so I have Lou 186 miles to the west, You guys east (350 to 450 miles). One fellow in NYS (70 miles)and Jim Ve3DCX north (60 miles) of me. Lots of times for me a 5 watter is no good. I needed something with a bit more stomp so that is why I built it. I am hoping this one will be as good. I spent today adding wooden bracing to the variable tuning caps mount hoping to eliminate as much as possible any wiggling. I also completed the antenna take off. Hopefully I will screw up enough nerve to out some fire in the wire in the next couple of days. I promised Jim VE3DCX a heads up when I do as he is a big vintage fan and a competent CW operator (NJ CW net) so he has an interest in this kind of rig.

I put some power to it. It works but wasn't pretty. Ugly note. It tunes well though. Sweet spot 7070kcs with the sniffer. Too little grid resistance (and getting warm enough to heat the varnish under it.) and too much grid leak cap I think. So I hooked the hartley back up and have been playing on 7063kcs for a bit. I will deal with the TNT perhaps tomorrow. I would like to get it is perfect as possible if I can. I would like it to have a nice note especially.

I went back at it today. Increased the Grid leak resistor and took it to ground or Cathode connection rather then pumping possible rf through it. I dropped the value of the grid leak cap also. It isn't exactly what I want but it is what I have on hand so for now it will have to suffice. Hooked it back up and tried it. It works. Not perfect but much better and certainly useable. Tuned up on 7049 and called CQ. Otherwise it has pretty good manners Doesnt wander and isn't particularly bothered bu my hand. Tuning is quite fast so i will whip up a LDV vernier (Gromet,) to drive the tuning disc type knob stolen from a 1931 receiver I scrapped. I am going to leave it on 7049 for a day or so. So if you want listen and see if we can work. I haven't measred power yet but will once I am happy with all the values. Going to have to spend some gold (Man I hate that! It runs against my Schwaben Blut) But all in all I am giving it a thumbs up.

Neat article, I have never made one from scratch but al in my DX60B I have reground moving them up to the freq of choice. For instance from 6995 to 7290. I am going hunting for a piece of quartz. I think I would like a scratch built crystal and crystal holder and a rig to match. It would be a nice addition to the shack.
CR Snelgrove was the manufacturer of choice my Dad used. I don't know why he chose them but it was he favourite supplier when designing.
I also am interested in ceramic resonators. How they are made and where they come from. Maybe an old teacup?

You are a patient man, Don. And talented, if you were able to move the frequency that far without the xtal losing its activity. It's critical to maintain parallel surfaces, difficult to do in a home grinding operation. Congrats.

Don't let it fool you - there's more to the technology than just sandwiching a flat piece of quartz between two electrodes. The quartz needs to be cleaved in the correct crystallographic planes, for instance. I don't know much about it, but I do know that much.

>

It's some pretty specialized ceramics that are piezoelectric, and I don't think there are too many (any?) that occur naturally. It would have to be a pretty expensive teacup (and most people don't need a piezoelectric teacup).

They could also get a shock (literally) if the cup ever broke. Don, just think of a crystal microphone, that is a piezo electric transducer. Or, an ignitor for a barbecue. Also the Sonalert alarm. Piezoelectric transducers work similarly to magnetic one in that they can be used to generate electricity when subjected to pressure or, create pressure when electricity is applied. So, they can be use in an oscillator at high frequencies or as filters also depending on the design, 73 – Mike

The edge is the trick. I made a little chip osc (a 7400) for testing(and spotting) I used the off freq crystals (just out of band) I had to make the new ones for the DX60B since all it came with was a 3605 or something. I didnt get them bang on .I think some one said my 3725 was a 1/2 kc high and I think my 7290 is a bit high but not that much. You have worked me on it so would know better. I used the same method we use in carb repair for warped mating surfaces. 600 wet paper , wet on thick glass. Took a long time. but it was interesting. The 40m is a bit stubborn but works ok. The other two were fine. You have to dress the edge like the original crystal or they don't want to star. Took a bit to figure that out. I took another untouched crystal and asked myself "what looks different here?" That is how I learned to make them work.
You are probably right about making one but I always think if someone else did it once why can't I? I think I am determined but my wife says stubborn and has a sign on the kitchen wall that says "Living with A German Builds Character" whatever that is supposed to mean. Anyway to that end I was telling her at supper about reading the piece and how it would be fun to try and make one even if it didnt work. I wondered out loud where I could get some quartz locally. (We are a limestone area.) She laughed, got up from the table and came back with a solid piece of rose quartz. I asked where she got it. She said on our last venture into Austria she bought it in a shop near the Donau river. She said if I could make the bottom flat so it would sit nicely I could steal a 1/4 inch or so. A crystal would normally be .030" to 040" or so depending on freq. Thinner if of course higher. My brother has a wet diamond saw and often cuts ceramic insulators for me so I will see if he can slice me a thin slice even if it is a bit on te thic side.. If it doesn't work it will at least be pretty. Heck, I need the exercise. One of my old ARRL handbooks has a chapter on it and I have read it so I have nothing really to lose by trying. What if it works? But you right. It isnt real simple for sure and it is probably a waste of time. I am just curious. .

Don's run off to Tahti with a Hula Girl. Still looking for a ham with a leathe. Tks, Lou

As some here know, I built a P-P TPTG rig some years ago. While this circuit has lived up to its reputation for good stability and tone, with two controls plus hand effect it is not a "Kelley contest rig".

Recently I acquired a pair of vernier drive 500 mmfd. Cardwells which I have temporarily installed in the rig. While they have helped with zeroing in on frequency, tank condenser hand effect is still an issue.

As you see below, I have installed an wood dowel extender which does away with this problem. While the extender does the job, wood lacks the pizzazz of Bakelite or hard rubber.

Does anyone here have a metal lathe able to make* an extender for me? I will provide a drawing and a length of 3/8" dia. hard rubber rod.

Payment/trades discussed directly.

What say?

73, Lou
VE3AWA

Yes, Lots of interesting uses. I live in a corn growing area and in the 1970s all the bird bangers SmithRoles sold were peizo ignited. There was a Formula one car. Maserati I think that used a quartz pezo electric flake for its ignition. It is in my old Design and Tuning of Competition Engines reference book. I think I know where it is , I will go look. Found the book but not the page (yet) Anyway they said the peizo flake would last an entire race but no more and each race was started with a fresh flake . It was Masarati or Matra or something with a M and a 12 or 16 cylinder race engine with insane RPM limits. I can't find it right now. Tis a thick book!
Anyway the peizo effect is a very interesting deal. I hadn't realized Hams played such an important role in their use and I see from the numbers, were for years the primary users of them. It was a very interesting article and thanks for sharing it. Maybe we should have a rock fest weekend as well. I know Mike has a crystal controlled rig. I have two running here, BE and breadboard (aside from the DX60B) and Lou has his BE he just dug out for tomorrow night. I am sure there are others. Might be fun to trip down memory lane just one more time.

Was able to make the net last night due to n ice storm here. Mike you wondered why the difference in signals. I checked geography. I am closer to you by at least 130 mi then the other two. That doesn't say a lot for my set up perhaps or I could just be in the wrong spot propwise. Or it could be the different radiation angle of the 80M vertical. Anyway i could hear you fne here other then the QRN. I am due north of Rochestor NY across the water exactly. (The old rum runners route, Picton or Milford Canada to Rochestor USA. told in the book Booze Boats and Billions) The others are south west and north west of me by a fair distance ATCF. Anyway the ice melted overnite and my long wire for my vintage stuff survived . Gonna try the new TNT this morning with the ice off. 7049 or up 5 if busy.
I had forgotten about the Novice roundup. I will put some fire in the wire Sat anyway with my rock rigs

Date: 2016-02-25 15:56:09 UTC
From: mattgoff54@...
Topic: 12782 Message: 12782

I bought a number of old qsl's from the 20s up to 1931. I thought it would be interesting to see what folks were using and I was right. Representation of the 210 tube is very high. Few of them state running 750v on it... Anyway I have a few older ones that refer to the tx as a "1DH" circuit. Maybe more obvious than I can see but I dont know what that is. Anyone?

Also whats the opinion on the pilot super wasp rx. I see one on ebay but I dont know what to pay for one.

Matt KC8ZQS

Thia is the auction https://www.ebay.com/ulk/itm/331781992568

Ill try to fire up the scanner on the desktop and post the qsl's in two photos. Need to get on the computer anyway to make my own vintage style card.

From: Steve
Topic: 12782 Message: 12790

Some of you may enjoy this old 16mm movie likely made in 1925...shows many Californian amateurs, their shacks, shenanigans and antennas. Clearly some of the guys were still holding on to spark as long as they could, with some of the scenes apparently set up to mock using tubes to generate RF.

The stills photo set, culled from the movie, also includes more description of the movie and locations.

The online video of the 16mm film - http://www.qsl.net/sccara/SCCARA%20in%20the%201920's.mp4

Selected stills taken from the film - http://www.qsl.net/sccara/16mm_film_stills.html

The movie is archived here: http://www.qsl.net/sccara/video_archives.htm

If anyone knows the meaning of 'WARA', seen on one of the hats, it's still a mystery apparently.

I have all of 29 and some of 28 here as well as early thirties. I recently read probably the same article or nearly similar. It could also be single element directly heated as opposed to the 45 say which is a dual element directly heated. By 1930 indirectly heated was already on the scene (56 etc) and in production built radios by 1931.almost totally. I found a reference to directly heated and indirectly heated tubes in the same magazine perhaps the same article so that is where I made the leap of faith from. Just so one knows where I got it. As we all know when building with directly heated tubes there is a whole different set of problems that come with it. I have a hartley with a 45 that is series cathode modulated by a 01A. I have to supply the heaters independently otherwise the cathode circuits dont work. With indirectly heated there would be no trouble. since the heaters are not part of the cathode circuit. So I think and I may be wrong, the concept of this was at this time on designers minds because the circuits by their very nature are and must be different even though they do the same thing. However it was my best guess based on the references in the articles. Someday I will reread t and see of I still think the same. Today have other fish to fry. I bought a second 211 for my 211 sets. I had the old one in the new rig the TNT so I put the new one in the old hartley rig. I fired it up and tuned it to 7049 where I had been working and my call light came on. I have a garage door opener control upstairs for the XYL and a receiver downstairs with a 4 watt light bulb where the garage door opener would plug in. If the XYL wants me she pushes the button. Works well. I got the signal alright. Apparently I wiped out the whole Tv Screen on key down.And during Jeopardy too! Never did that before. .So more stuff to sort out. I kept the sked with Lou but he had a snag too. So I am sitting here tonite humming that old Carlene Carter song "Did I Shave My Legs For This?" ;>) Somedays are great. This one wasn't.

I've lusted after the Super Wasp for many years, but the price has always been out of reach. I keep telling myself I've already got plenty of toys, and I do.

I tend to be a "bottom feeder." I've always taken in the inexpensive, neglected, abused sets no one else seems to want and give them a home. They've always been swap meet finds or gifts from hams that no longer want them. Some of it is old homebrew equipment built by some ham or hobbyist long ago.

My SW-3 cost me $45. It was in rough shape but restoreable. Jim Kreuzer sold ("gave?") it to me at one of the AWA conventions early in the previous decade. Last August I bought a pair of restoration projects - a Pierson-Delane (i.e., Patterson) PR-15 and a Breting 12 at the Boxboro MA New England ARRL Convention flea market. $20 for both. I had not intended to bring home any more "boxes" but for the price I couldn't say no. Last fall I worked on the Pierson-Delane receiver and it became a wedding gift for my friend Bruce W1UJR. The Breting is on the bench now and I've pretty much completed the electrical work and it's working, but I need to do something about the meters, which are stuck. Also, one of the meter housings is missing, and the other is in real rough shape. I bought a pair of period meters recently with housings that might be able to be modified to accept the innards of the Breting meters, assuming I can fix the sticking movements. I also need to take apart the tuning mechanism to clean and lubricate it. The two halves of the split gear are stuck together, so there is backlash.

I've attached a photo of the Pierson-Delane. I had to fabricate a substitute for the dial plate, which was missing. It's far from perfect but it's the best I could do with what I could come up with. I have a lot more patience and talent for the electronic work over the "mechanical" work.

73,
-Larry/NE1S

That 203 is very tempting. I really may not be eating. Love the pip top 203's and 211's. Anyone know when the "50 watters" got rid of it? My sylvania 203 looks nothing like that, has the thick black plate. I would guess maybe a late 30's version.

Then there's this QST cover pair from jan/Feb 1931. It looks like the big rig, besides catching cobwebs while the OM had QSOs, lost a meter and a capacitor to the Hartley.

Just so you don't think we're asleep up here...

K0SM and I have partially-completed power supplies and my #27 tubes arrived at the PO today. Andy's supply is old school and I opted for a regulated HV design drawn by W3NLB and N6GA (<300vdc, <100ma; CQ Magazine online, June 2011). Cam is very kind and has sent me his HV supply that will power a tube rig here. Andy has already built his #27 oscillator and I'm waiting for the price of copper to decline :)

And check out the wooden beehive insulator, that might see some use.

If it's not OK to attach pictures, please let me know and I apologize in advance.

Just so you don't think we're asleep up here...

K0SM and I have partially-completed power supplies and my #27 tubes arrived at the PO today. Andy's supply is old school and I opted for a regulated HV design drawn by W3NLB and N6GA (<300vdc, <100ma; CQ Magazine online, June 2011). Cam is very kind and has sent me his HV supply that will power a tube rig here. Andy has already built his #27 oscillator and I'm waiting for the price of copper to decline :)

And check out the wooden beehive insulator, that might see some use.

If it's not OK to attach pictures, please let me know and I apologize in advance.

73, Dean, NW2K

Tuning can be a bit tricky on these old transmitters. Lou showed me a photo and I noticed he was using a grommet beside the dial for an easy reduction. I tried it on my first TNT and it worked nicely so I took it to the next step. This week I installed it on the 211 TNT I just built (AKA Louis II TnT, since his 203 experiment inspired it.) One needs only a nylon spacer 1 inch long (or anything similar) and 1/4 inch diameter. A 1 1/2 " long #6 screw and a nut. A grommet that fits on the 1/4 spacer snugly and a knob (1/4 " hole with set screw.)
You also need a wide disc on the tuning cap like the old numbered bakelite ones or anything similar. Place the grommet on the spacer. Take a drill that is one size below the #6 screw and with it in the drill hold the grommet snug to the disc (disc in the groove and drill the hole in the bracket or panel. Put the # 6 screw in the drill and spin it against a file or coarse sandpaper till the outside of the screw head is slightly reduced. this stops it from dragging inside the knob later. with the grommet in the groove screw the # 6 screw in the hole. It will cut a nice thread on the way that will not be loose like if a tap was used but "neizen-teit". If you wish put a nut on the back . Slide the chosen knob over the screw head onto the 1/4 inch spacer bushing and tighten the set screw (not too tight , just enough to grip. You know have a very smooth working tuning cap drive reductions that if you choose your knob right looks period correct and will work very well. It is now my goto method. don VE3LYX. Cost very little $ works very well.

As discussed earlier I was going to try and make a functioning crystal. I asked my brother if he would try cutting the quartz on his diamond tile saw. he stopped by today and picked it up We discussed where the natural fault in the stone appeared to be and he got me a couple of workable pieces. This is of the thicker one. I will do a test run with the thinner one. I know I have to have the shape right of they dont start well so i am working at getting the piece to that shape , starting with the rough cut slab and slowly wearing it down on carborundum paper to get the shape right before I start grinding it for thickness and freq. Today I was calling CQ on the 211 TnT (7070kcs) and then rubbing on it for a minute in between. It is going to take a lot of minutes but I am going to try it. I also have to make a holder with a contact on each side. Meanwhile I finished the 80M vertical today. I am now happy with it all as is. If it doesn't blow down in the terrible wind we have right now I will be using it with the BE rig (3542) and the TS830S Kenwood on SSB. donVe3LYX

>where the natural fault in the stone appeared to be

Macrocrystalline quartz (the familiar ‘quartz crystal’) does not exhibit cleavage planes. It fractures irregularly. Other varieties such as agate or flint will fracture conchoidally.

From what I understand, selected quartz crystals are cut on a particular crystallographic axis and then ground and polished to the thickness where the desired piezoelectric behavior occurs.

A couple of new words there. Anyway, please understand I do not think I am building a perfect device. I am trying to see if I can make a functioning crystal. Period. The Crystal is a piece of Rose Quartz which came from the Danube (Donau) Valley in Austria. We got it there ourselves und hierbrungen. It may be all wrong and a total waste of time HOWEVER in my lifetime I have learned to try everything I think of. I am more then willing to put in the time and effort even if it turns out to be for nothing. I always learn something in the process. The number of times some of these experiments have turned out to be successful or led to success is even to me surprising. I have heard my XYL tell people"Don't tell him it won"t work. That is just like waving a red flag in front of a bull." That was in the field of Race engine development and we were able to achieve power levels with seemingly nothing using science and math and careful machine work that are still valid and surprising even today. Evey step of the way in a couple of projects someone was suggesting that won't work or of it was that easy someone would have already done it. I am sorry but I am deaf to that. If this doesn't work you can all have a good HA, HA at my expense. Failure I am not afraid of. Not trying is what I am afraid of. So we will see. It will take quite awhile to make it. I know. When re-efinishing old crystals to move them up into the 40 meter band took me several days of rubbing and testing for each one. This will be a lot more work then that. I will just poke away at it in the shack while I am "reading the mail" The biggest trick it not to get in a rush. I make my own violins for playing in public and abit of studio work. It takes about a year. Not particularily difficult but no way to hurry it up. There is something interesting about that. I just grinned now. I was thinking how n expert (that is always someone who has never made one) told me I couldn't just make a violin out of normal wood. It have to be spruce cut from the Swiss Alps on the north side in temperatures below -3C and the bottom must be Bosnian maple or something hand sawn in midsummer at night. Then he asked me where did I get the wood for mine. I told him Home Depot and he almost passed out. The wood for the last one I cut from my farm myself. So I am no stranger to doing it all wrong. Anyway we will see what happens. Probably nothing BUT what if it works?!!!!!!!! I find this sort of thing incredibly interesting.

Don –

You are of course welcome to go down any path that you like to attempt to solve a solution to a given problem, however, when someone offers help, I still feel you should at least thank them even if you are not going to listen to them. Using the “Edison” method of engineering is fine, if you are Edison with infinite funds. Us normal humans however like to rely and tried and proven methods that can be demonstrated physically and proven analytically. As far as violins, I am sure they do not all need to be a Stradivarius, and you have demonstrated that to some, the other extreme sounds acceptable as well. As Einstein said “if we knew what we were doing we would not call it research”. 73 – Mike

Thank you everyone who has offered references and suggestions. I will check them out. I am close to have a grinding blank made. Freq I dont worry about too much because my test osc is a chip oscillator and will run at what the crystal is without setting it.All I need is a rx that will tune to it. Once I get the blank to ready for grinding I am into familiar territory. It is interesting , my brother Dan told me when he was cutting it on his diamond saw even though it is rose colored the whole thing glowed bright blue/white. That gives me hope anyway. We shall see.
don
Also Neil, Thanks for the tips on the tent pole vertical. It is now completely finished and working and survived a fierce windstorm last night unscathed. .

No but I can tell anyone who wonders moving old crystals up in freq so they can be used is not that hard. It is just a lot of work. With this one, cut from the stone , the big trouble is getting the blank parallel with its self. Or unifirm thickness. I have set it aside while I come up with a plan for that however I did clip it in the test osc just before supper . It uses tiny gator clips so I put a small pad of paper on one side of each clip so I could make contact on one side but not the other. so with a paper on opposite side of the blank I could put it in the osc circuit. Something is definately happen as RF was being generated and could be heard distinctly on my grundig sitting nearby and tuned about 5.2 meg (Loudest) but it was dirty RF. and not a clean clear freq. I was not surprised because the thickness is not uniform. I was however more then just a little surprised that the oscillator fired up.
My whole premise was I wondered out loud to the XYL if a early ham could have found a chunk of quartz and made a Crystal. She gave me the Austrian crystal telling me to take a slice and try if I wanted. I wanted. There is something about exploring the early days that is very interesting. I gotta think my way through the next step. Gonna read some of the stuff you guys linked me too. I need to make a holder so I can true the blank.

I read the entire piece that Niel showed me. there is a note there that says imperfections in the crystal may cause all sorts of weird frequencies. That may be where I am at although I will see it through. This is why they used the Quartz Steve recommended I guess. I was curious could it be done with any quart a man could find. Probably not. But there is enough maybe to stir my curioisty. What really got my attention is the notes about self rectification of transmitters and oscillators. I have read a bit about them even into the 1930s QST about ARRL Lab tests which said properly done they were just fine. This article mentioned they can present an almost Pure DC note. Has anyone built one? If I understood the article corectly the finl one the show is a pair of 210s driving a pair of 203s and not a rectifier or filter cap in site. I kinda understand how it works and pse dont nobody say raw ac on the signal, It says and I have read it elsewhere nearly a pure DC note which as many know is not easy to do even with accepted designs straight out of the Handbooks. I don't have any 210 tubes but I do have some 45s the poor boys 210. Anyway was a wonderful read.

Don –

Just be careful. You may get the circuit to oscillate and it will have nothing to do with your cut crystal, just due to the capacitive effects between the contacts. 73 – Mike

That is possible for sure. I did try it with just the contacts and no crystal and there was just a click and little else when I pushed the button but it is also possible there is some conductivity in the rock that is just completing the circuit as the clips would still be in the same position. I was quite frankly surprised it went off and was as strong as it was but allow for false stuff to mislead me. It was kind of a half hearted test just before dinner which I really didn't expect to yield any results but did it just for fun.
I built the chip oscillator several ears ago for spotting crystals to my no digital readout receivers so I can be bang on instead of somewhere nearby. It works pretty good for that and cost only a few cents at the time. I see I still have a bunch of 7400s in my IC drawer. I must have got a deal. The aluminum face plate of the project box is the radiator or ariel so you have to be close when spotting.

BTW testing today on 7070 when it is open with the 211 tNt should anyone have a set of "ears". Quarter past each hour I am home.

recommended I guess. I was curious could it be done with any
quart a man could find. Probably not. But there is enough
maybe to stir my curioisty. What really got my attention is
the notes about self rectification of transmitters and

oscillators. I have read a bit about them even into the 1930s QST about ARRL Lab tests which said properly done they were just fine. This article mentioned they can present an almost Pure DC note. Has anyone built one? If I understood the article corectly the finl one the show is a pair of 210s driving a pair of 203s and not a rectifier or filter cap in site. I kinda understand how it works and pse dont nobody say raw ac on the signal, It says and I have read it elsewhere nearly a pure DC note which as many know is not easy to do even with accepted designs straight out of the Handbooks. I don't have any 210 tubes but I do have some 45s the poor boys 210. Anyway was a wonderful read. donVe3LYX

I was going to suggest this test, as I really suspected it was the osc.
cicuit taking off on its own with no influence from the hunk o' quartz.
Guess I was wrong (maybe).

BTW, quartz xtal holders depend on capacitive coupling to the xtal -
that's why you always see copper or steel plates on each side of the
xtals. On more modern xtals you have conductive layers that are plated
or vapor-deposited onto each side of the xtal, and the leads make
contact to those layers. It's still capacitive coupling. There's no way
to make an ohminc contact to a quartz xtal, since quartz is an
insulator. I'm not seeing how you would get sufficient capacitive
coupling from the typical alligator or crocodile clips. Maybe your clips
are a different style?

You can also use a 7404 inverter chip or a host of other logic chips. I
think what you're referring to is a ring oscillator with the xtal in the
feedback bath/ring. If you eliminate the xtal and replace it with a
short circuit it will oscillate at the maximum switching frequency of
the devices. If you replace the xtal with a reactive element (capacitor
or inductor) it will probably oscillate at some frequency as well.

A Schottky (e.g. 74S00) or advanced CMOS (e.g. 74AC00) device will allow
the oscillator to oscillate at higher maximum frequencies than are
possible with the standard TTL devices like the 7400.

Remember, there are ceramic capacitors also. In a simple feedback oscillator using logic gates they can take off easily. Wonder if Don you can measure the capacitance of your crystal and contacts and then replace it with a same value capacitor. 73 – Mike

no I dont have a capacitance meter. (it puked) Doesnt really matter . Until the crystal can determine a freq it is just a rock even if somewhat conductive. It just surprised me as I was prepared for nothing. I guess I do know the chip osc will not make Rf with a dud crystal as tat is how I tested them when grinding the first ones I moved. As well as grinding the thickness you have to dress the edge if you remove much or they wont start at that low a power. Anyway i set t aside fornow as have been hard at work trying to improve my TNT 211 rig. It is getting better but hard to tell when you are in the same shack. Next test 7070 in 3 minutes.

So I am curious, Do the test oscillators you fellows built run with no crystal in them. Is that what you are telling me? I know mine won't run with a dud crystal from when I was teaching myself to regrind them. If the ones you guys built do perhaps it is a slightly different circuit. Whatever.
Anyway I worked on the rock a lot yesterday while testing my 211 TNT on air. Here is an example of what I started with and where I have gotten so far. I hope by next week I can start the final rub to finish.
Over in the corner are my two monster rigs the 211 Hartley near the wall and the new 211 TNT closer to the camera. I have been testing the TNT on air quarter past on 7070 every hour I am in the house(and awake). Have to play at a funeral today so will be on a reduced schedule til late afternoon. Need a sig report from the rig . The TNt does not have the same power out as the hartley. I am mulling that over to figure out why but I think it is not bad sound wise but really don't know.

Anyone have a line on a good old time QSL printer? Or someone who comes close? I used to make them on the computer but digital just doesnt look right. I thought about having a stamp made and doing the stamp and typewriter thing, as I have a few Underwoods in good order here. But having some nice ones printed would probably be best.

From: dulmagedon@...
Topic: 12844 Message: 12844

I have gotten the 211 TNT working fairly decent. At least as near as I can tell in here. Input is about 45 watts. Output I have no idea. In shack radiation on he FS meter shows nothing but the rig can be heard several miles away so I know it is getting out. I have been testing it on 7070 between the top of the hour and 1/4 past when home. (next9 am)Thought I heard Paul in there once too but maybe it was just wishful thinking. (A test signal an ID, then gone) Hard to get a good reading on a single wire feed . I tried a light in the line but got nothing indicated so I am not sure. Will do further testing this morning. maybe compare it to the 211 Hartley. It has higher input from the same PSU so one would hope output would be similar. Still until you actually work someone you just don't really know. It lights the sniffer so strong I thought it might blow and the ant out coil is in that same spot. So it is making RF but is it doing anything?

Thank you Doug, It helps so much if someone listens. It saves days of posts and testing. I tested as wwas at 9 am then did a sweep with the sniffer and wound up moving the grid coil higher it was peaked in band but just. Antenna current bulb now lights and note is much cleaner. AND I got a hit thanks to VE2CW. Gotta check him out as he signed with a typical German expression tacked on after his 73. So we're good. It werks! T'would be a long haul to you but stranger things have happened. Any copy at all?

Heard from the VE2. Said he liked the sound and wants another. I am going to have to dust off my French. I havent spoken any since 2005. I had to scratch my heard when emailing him. I ought to be ashamed of that. He is Ok in English but not comfy. I should be able to talk to him en Francais so it will be easier for him since he was kind enough to step into my world to help me out. I used to be Ok in it when younger. Never great but OK. Felt like n idiot when I couldn't remember the words.
This afternoon I am going to try a test on 7045 (up 5 if busy) to see how it operates on the lower side of its sweet spot. (grid coil natural freq) Shooting for 4PM and then 6 PM.

Hallo Lou, and all peoples in the group!

Thanks so much for accepting my request and proud to be between you.

I'm a licensed Ham since 1973 (end of) and begun my Ham life with tubes but at that time I was quite ignorant about Electronicas and bias and desing, etc...and so I copied schematics and anyway was able to be on the air with my Geloso G4/220 general coverage RX and Geloso VFO 4/102 2 W out and later added an 807 in order to get more QSO and...DX...hi

But the timers lead me to solid state equipments and also to an Electronic and Telecomm University degree and some diferent jobs in the field (TLC antenna, sat antennas, radars and so on). Late I left companies world and went to High school and become a teacher in Electornic and Automation, but...since 2013 I moved from Rome to a rural very little village in Central NW of Italy (mid mountain) and..went back to my roots...the TUBES...and wires antenna as it was since 1973.
Slowly I left also commercial RIG's and last, the FT817 was sold 5 months ago, so now I've just homemade and some RX I love as the are specials: an R&S EK07, a Siemens E311 and a Collins 51J4, and now I'm going to make a new homemade (made several solid state in past) all tube RX too, following the design idea of Collins receivers.

Now I'm curently using a single tube (6DQ6) TX (abt 12 W) crystal controlled, and I'm just arriving to use an old BC221 frequency meter/oscillator as a main VFO insteda the rock xtals I have now.

So this is my story for you.

Hope to meet you someday on the air, and to learn more reading your very nice and interesting post on the grou.

Wish to everyone a nice sunday and a pleasant evening.

Best 73 and regards

Alex I5SKK ex I0SKK

This afternoon I am going to try a test on 7045 (up 5 if busy) to see how it operates on the lower side of its sweet spot. (grid coil natural freq)
Which reminds me...

GM All,

In the one-tuber TNT article, Grammer wrote that the grid coil should be wound so that the lowest Ip is at or near the band portion of operation. In the P-P TNT article, he states that spot should be just beneath the lower band edge.

Why so?

73, Lou

Now I'm curently using a single tube (6DQ6) TX (abt 12 W) crystal controlled, and I'm just arriving to use an old BC221 frequency meter/oscillator as a main VFO insteda the rock xtals I have now.

So this is my story for you.

Hope to meet you someday on the air, and to learn more reading your very nice and interesting post on the grou.

Wish to everyone a nice sunday and a pleasant evening.

Best 73 and regards

Alex I5SKK ex I0SKK

I don't know what his reason was as I don't have much of that literature and don't generally build from plans, but I know that ideally you wish to operate near the middle of the grid coils natural freq. That is where the most power is. You can test that with a RF sniffer bulb as Matt will also attest to. It is quite obvious. If you measure antenna current, which I do using a lamp bulb in series with my single feed wire to my long wire, you will see very plainly the relationship between grid coil's natural sweet spot and the power out. The further you are from the sweet spot the poorer the power output. Same as if you were running a TPTG(which I have) and the grid was tuned too far from the plate tank freq. I had the grid just to the end of 40M and even at 70 khz up power was down considerably. So I dug out my trusty in series ant lamp set up it confirmed it. It was bright right at the edge of the band 7004 or so. At 7070 nothing , no light (4 watt lamp bulb) even though it was producing RF. So I began step by step unwinding the grid coil. It is now brightest around 7050 and still strong at 7070 and even down to 7034 where I have been already.
Meters are often bothered by RF fields so when I need to know for sure I use lamps as they don't lie to me. Christmas tree bulbs are a great source. Whether I just didn't have anyone listening earlier which is very possible or what, I know that after moving the grid coil up to be centered where I like to operate I am getting a reply almost every time.
Now for my humbling moment. I am unable to get a usable signal from the homemade quartz crystal. So I will take my medicine like a man. I am sorry I was wrong. ;<(
Twas very interesting though. At least to me.

So you did get some signal, it was just unusable? What criteria do you have for a usable/unusable signal? If you thought it was unusable, how much signal did you have?

Signal is strong , just no real definition. Centered near 7200 but spread overmuch of the dial. Probably would make a good noise bridge or something. Since all the rock in my Dx60B reground myself and several of you have talked to me or heard me on it I know this one is no good. The crystal is not clean . I can see a defect in it however it was as I said fun to try. What if it had worked?
Meanwhile had the TNT on again. I am getting a hit everytime now. Last report was S8 no chirp and freq stable.
A little cloud in with some success is ok by me.

I had clipped my quartz in the testor and as a lost ditch effort before trashing it I made a plywood hokder with a spring clip. playing with the tension a bit I tred it. I could hear it was working but very faint. Tuned across the SW1 band of my Grindig crank radio and found it.just under 5 mcs. Very difinate (otuching it changes the freq or kills it). Not wonderful but definately there. If the light improves I may make a You tube videio and pop it up there. The XYL is thrilled that her rock now "talks"as she put it. It makes the radio squeal if real close. Tisn't too strong but very definate. I am havng an off day
so i will just set it aside till I feel human again but anyway. Can you find a quartz rock and make a crystal that works. Apparently yes. If you were a rock hound like Steve and knew what to look for in a core I think it could be done with even more success. Me at the moment I am worn out.

Hi Don, What circuit design are you using? If you can add some additional feedback, you may be able to convince the xtal to oscillate more vigorously. This technique works fb, when attempting to convince non-overtone rocks, to oscillate at overtone freqs---3rd, 5th, 7th, and perhaps even higher order overtones. The feedback level becomes very critical at the higher order overtones. The xtal will no longer control the oscillation freq, if the feedback is excessive, and too little feedback results in no oscillation at all (near or at the selected overtone freq.) The same info applies to fundamental operation, with xtals that suffer from low activity issues. GL & 73 de ron n4gjv

Hallo Lou, and all peoples in the group!

Thanks so much for accepting my request and proud to be between you.

I'm a licensed Ham since 1973 (end of) and begun my Ham life with tubes but at that time I was quite ignorant about Electronicas and bias and desing, etc...and so I copied schematics and anyway was able to be on the air with my Geloso G4/220 general coverage RX and Geloso VFO 4/102 2 W out and later added an 807 in order to get more QSO and...DX...hi

But the timers lead me to solid state equipments and also to an Electronic and Telecomm University degree and some diferent jobs in the field (TLC antenna, sat antennas, radars and so on). Late I left companies world and went to High school and become a teacher in Electornic and Automation, but...since 2013 I moved from Rome to a rural very little village in Central NW of Italy (mid mountain) and..went back to my roots...the TUBES...and wires antenna as it was since 1973.
Slowly I left also commercial RIG's and last, the FT817 was sold 5 months ago, so now I've just homemade and some RX I love as the are specials: an R&S EK07, a Siemens E311 and a Collins 51J4, and now I'm going to make a new homemade (made several solid state in past) all tube RX too, following the design idea of Collins receivers.

Now I'm curently using a single tube (6DQ6) TX (abt 12 W) crystal controlled, and I'm just arriving to use an old BC221 frequency meter/oscillator as a main VFO insteda the rock xtals I have now.

So this is my story for you.

GA Don, I am sure you know the fact that not all Quartz exhibits the Piezo effect. A good portion of the materialused during WW2 was "grown". My imperfect recall is that Brazilian Quartz was the original raw material.A small amount of Quartz from Arkansas exhibits the effect. I don't think much natural Quartz is used anymore. The original Piezo effect was noted by Pierre Curie (husband of Marie Curie and co-discoverer ofRadium).
  Might I suggest you remove the rock altogether and see if it still oscillates. If it only oscillates with theQuartz slab in the circuit, my hat is off to you. Good Show!

Don,

Very interesting. Thanks for making that video.

As I had said in an earlier post, the coupling to a crystal is capacitive, not by electrical "contact" (you can't make an electrical [ohmic] contact to an insulator). In any older holder you will always see a metal plate on each side of the xtal - that's for capacitive coupling. On newer xtals there's a metal coating on each side of the quartz that serves the same function. I'd suggest cutting a couple of flat sheet metal pieces the same size as the face of your xtal and sandwich the xtal between them, then put that in your holder. You could even try a couple pieces of aluminum foil just as an experiment.

In the way you've designed your holder you'll get some capacitive coupling (it's hard to avoid), but not nearly as much as with the metal plates, and it's not uniform across the xtal. Since something appears to be "happening" now, it'd be interesting to see what the results would be if you were to add the metal plates.

I am off on a new adventure now. My Arc5s which I use from time to time ,mostly on AM but sometimes CW (Linc Cundall event) use a hb power supply. Actually it isnt true homebrew because it is right out of several ARRL handbooks and is known as The Economy Supply. It supplies all required voltages from a single unit. Because I wanted to be able to leave it on standby and needed 12 v filament for which it or they all have been rewired I added a separate 12 volt heater transformer and I can switchh on or off the hi voltage transformers primary but keeping it at the ready so to speak. the thing has a hum problem. It got real bad recently when I added a extra socket for power for the no 19 (which I never used) Yesterday I removed the extra wiring and cleaned up what was there. It has a choke and good filtering and uses a diode bridge. One would think being built by the book it would be perfect and quiet but it isnt. I moved the tX away from the power supplies magnetic field (Big transformer) and that helped but I can still hear some crap on the in shack monitor that I don't like. It could be the monitor is just too close and that under normal use it would be OK but I doubt it.
I suspect I need to bypass the bridge with 01s at each diode or maybe even make a new one. I can accept a bit of hum on these old rigs but not to an objectionable level. So I am looking for tricks to kill it. I use a modulator in the ARC5 key hole (yes both my ARC5s have been modified for CW key jacks long before they arrived here) to modulate it. It does a reasonable job . I have worked Dave KA2J south of me here near Sryacuse several times with no difficulty. In fact he spent sometime helping check it out when I first got it going. I would like to make it better so I can use it more often. So I am open to any hum killing suggestions that worked for any of you. I will write them al down and go through them if possible till I am happy with it.i If you need to hear it the rig is 80M (and I have one for 160 as well.)

Don,

The Economy Power Supply is a well known and much used circuit, and should work well for your Command Sets. The most likely reason for a recently developed hum would be deteriorating filter capacitors. Many years ago, when silicon rectifier diodes were not well matched and you were using several of them in series, it was good practice to shunt extra capacitors across them, but these days if you buy a batch of diodes together from a distributor they should be sufficiently well matched so that extra caps are not necessary. If diodes "go bad," they usually just short out. You could discover that with an ohm meter. Measure across them with the ohm meter probes in one direction, and then reverse the probes and measure across them again. A shorted diode will show the same, low resistance in both directions.

Jim Hanlon, W8KGI

Hi Jim & list,

The capacitors across silicon diodes are not just for voltage equalization of transients across a diode string, for protection. As you indicate, the tolerance among diodes has tightened up significantly from the early days, and with modern diodes they would be unnecessary were this their only purpose.

The other reason why an RF bypass across diodes (even if they are not part of a series string) has not gone away. Silicon diodes, especially modern ones, switch on (off) very rapidly as the voltage across them exceeds (or is reduced below) the turn-on voltage. This can create harmonics of line frequency well into the HF region, and can create artifacts with receivers, as well as transmitters. A parallel cap on each diode helps to suppress this.

73,
-Larry/NE1S

Don,

I should have done this days ago, but I've been a little busy with other things here at home.

From the looks of your "crystal holder," it would seem that you need a better one to couple well to your home ground crystal.

I have a Bliley BC2 crystal holder. It is from the middle 1930s. It looks like a small hockey puck with two pins coming out the bottom spaced 3/4 of an inch. They would fit into a five-pin tube socket. It has a screw-on cap, so it's easy to get to the inside. On the inside is a stack of electrode/crystal/electrode. The electrodes are 1 inch by 1 inch metal plates. The top electrode is held down by a tab, screwed down to one side of the holder outside of the electrode area. It should be easy to take the electrode/crystal assembly apart and insert your own crystal numerous times. I can take some pictures and send them to you if you are interested. I haven't checked, but it is likely that this holder may also include a crystal.

This would be a good holder to use with your experimental crystal if it is 1" x 1" or smaller. I would be happy to send it to you. If you are interested please send me an address I can mail it to.

I also remember reading about a grinding technique that you might be able to benefit from. If you put an "antenna" such as a piece of aluminum foil or a metal plate underneath your grinding surface and connect it to a receiver, you should be able to hear some RF noise at the current frequency of the crystal while you are grinding it. You could check this out with a known good crystal.

73,

Jim Hanlon, W8KGI

I have over the last 30+years built a few of the Economy supplies. Maybe 5 or 6. They work yes but hum is to me anyway not at an acceptable level on these WW2 transmitters. By passing always seems to help. It is my opinion but I think a vacuum tube diode behaves quite a bit different then a solid state diode. I think the switch point is softer (in a tube) if you will allow me that expression. I think the solid state is so definite it creates some of its own problems. An Am transmitter seems to find hum while a rx will run on the same supply and be fine. Sometimes I wonder did ARRL ever build and use one or was it this should work lets put it in the book deal. often real life has a few curves the planners didnt see. I know from my own career. First you concive the plan. then design it, then build it and then perfect it. Of course if one doesn't do the second last step the final section gets missed too. Power supplies tick me off because I think they should work a lot better then they do.
I hope someday I won't feel that way. I could just buy one I guess but that would be cheating and i would lern nothing. Anyway, so far, I have bypassed all the diodes with .01s , Doubled the filter MFD value, installed a different soft start resistor and am currently building a voltage divider (both ends connected) to supply screen and osc voltage as well as PA voltage. I am also when my parts order arrives going to build a hash filter. I had to do this with my No 19 supply and while it is now decent it could still stand improvement. It was not usable on the economy supply. This ARC 5 one has always had a hum issue and I intend to get rid of it if possible. I already checked the diodes , it was first thing I did actually and inspected the caps. They are relatively new and not old nos stuff. If I have to replace them at the end of this I will but I think they re good. I have spares , but these are better quality then the spares so I will take all this info onto account as I poke through each step.

Man that crystal grinding recr monitoring deal sounds interesting. I have old Blileys here, Jim . Thanks for the offer. In fact I don't know if you were around then but I made my own VF1 from one of those, casting the new top section in my home foundry and making a device to vary the spring pressure. I think there is a picture of it here in photos from several years back when I was in the crystal grinding mode and experimenting with such before Lou dragged me kicking and screaming into the wild world of self controlled oscillators.. A fellow who lives back near the mines north of here (we say "Back North") gave me boxes of old radio stuff and in it were several old round Blileys and some of the 243 types as well. I used the 243s before for making the crystals for my DX60B (3705, 3725, 7290). I took crystals that were just below the Ham 80m and 40m bands and moved them up checking them on the test osc I built (that is the same one in the video.) as I went making sure they would still work as I moved them up. It took a long time but once I got one working I was hooked and finished the other two The 243s have a similar construction as well. However the actual crystal support is a bit different.You know I thought about using one of the old holders for this rock experiment but since my original premise was to see could a functioning crystal be made by anyone using simple and readily available stuff I couldn't bring myself to use a commercial holder. It is probably my square headed deutsche blut but tis how I thought. I was as close a had disassembled an old 8005 kcs 243 but thought that wouldn't be right so I put it back together. Anyway I am not planning to use that homemade rock I just wanted to see if it could be done. The holder was built in a few minutes and the clip was in my hardware drawer. Maybe next winter I will make a more pretty one. My curiosity is at least for the moment satisfied. One project still hanging fire here that I wish to do before I move on to the big station in the sky is revive the no vacuum tube deal and make an oscillator with it. And I promised Doug I would do some more measurment next time I had it running but I have been having so much fun with the AWA events and the No 19 while I have worked a bit on it (soup can lid tuning cap is partially built since Christmas) something always seems to get in the way. I believe it is called F.U.N!

Don, you are exactly right. A vacuum-tube diode has a higher "internal resistance" which absorbs the energy.

I have had hum problems with the "economy supply" concept when I tried to use a common filter in the negative lead. When I have a separate filter in each positive output I have not had problems. Just my experience.

Don,

I should have done this days ago, but I've been a little busy with other things here at home.

From the looks of your "crystal holder," it would seem that you need a better one to couple well to your home ground crystal.

I have a Bliley BC2 crystal holder. It is from the middle 1930s. It looks like a small hockey puck with two pins coming out the bottom spaced 3/4 of an inch. They would fit into a five-pin tube socket. It has a screw-on cap, so it's easy to get to the inside. On the inside is a stack of electrode/crystal/electrode. The electrodes are 1 inch by 1 inch metal plates. The top electrode is held down by a tab, screwed down to one side of the holder outside of the electrode area. It should be easy to take the electrode/crystal assembly apart and insert your own crystal numerous times. I can take some pictures and send them to you if you are interested. I haven't checked, but it is likely that this holder may also include a crystal.

This would be a good holder to use with your experimental crystal if it is 1" x 1" or smaller. I would be happy to send it to you. If you are interested please send me an address I can mail it to.

I also remember reading about a grinding technique that you might be able to benefit from. If you put an "antenna" such as a piece of aluminum foil or a metal plate underneath your grinding surface and connect it to a receiver, you should be able to hear some RF noise at the current frequency of the crystal while you are grinding it. You could check this out with a known good crystal.

Hi Roger, I had noticed that difference in some of mine (round Blileys)but I had not realized the 80M 40m band was the defining difference. I wonder why that is. I want to build a big tube crystal controlled rig and I have some really old huge rectangular crystals . One is 3500kcs so I could sneak safely into 80M easily I think with a bit of rubbing. I had thought of a 811 or 811A but am getting to really like the 211 tubes after building 2 rigs with one. I will have to find another socket.
Speaking of 211 rigs, I got a QSl card from a fellow who worked the new TNT and he gave me a 588 and said Rig has no chirp and is very stable. So I decided to plug my simple modulator in (That I built for and use on the ARC5s) and try modulating it. XYL monitored it from a short distance and said it was very clear on both the digital rx and the anolog rx. Since she is a retired school mar'm and cuts me no slack ("I can't hear you" or "you're mumbling")I am encouraged. I may try to redesign the modulator for a pair of 01As (two 5v heaters wil work with the ten volt heater transformer and the transformer I used has two ten volt windings) Then I could have period correct modulation in the B neg feed.
I would probably drop the crystal mic for a carbon mic and battery circuit just to be honest which would allow me to drop one tube amp section so two triodes could be made to work I think.(or 4) Or use an earphone for a mic. Anyway it appears to work but really need someone at a longer distance to give it a fair test.
Larry,
My impressions of the neg lead filtering on the eco PSU are similar to you comments.
In the No 19 PSU I finally dropped the choke altogether with good results. I read a piece by a Heathkit designer of why he did and recently I read a one page article by James Millen written in 1938 on power supplies that confirmed many of my suspicions. PSUs are a weak spot for me which I am trying to cure. Only have one I am really happy with (My linear's) A few are Ok or reasonably good but not content yet.

Don,

Are you building the Nov1952 design, but using diodes in place of rectifier tubes?

Tnx,

Robert

> I have over the last 30+years built a few of the Economy supplies. Maybe 5 or 6. They work yes but hum is to me anyway not at an acceptable level on these WW2 transmitters. By passing always seems to help. It is my opinion but I think a vacuum tube diode behaves quite a bit different then a solid state diode. I think the switch point is softer (in a tube) if you will allow me that expression. I think the solid state is so definite it creates some of its own problems. An Am transmitter seems to find hum while a rx will run on the same supply and be fine. Sometimes I wonder did ARRL ever build and use one or was it this should work lets put it in the book deal. often real life has a few curves the planners didnt see. I know from my own career. First you concive the plan. then design it, then build it and then perfect it. Of course if one doesn't do the second last step the final section gets missed too. Power supplies tick me off because I think they should work a lot better then they do.
> I hope someday I won't feel that way. I could just buy one I guess but that would be cheating and i would lern nothing. Anyway, so far, I have bypassed all the diodes with .01s , Doubled the filter MFD value, installed a different soft start resistor and am currently building a voltage divider (both ends connected) to supply screen and osc voltage as well as PA voltage. I am also when my parts order arrives going to build a hash filter. I had to do this with my No 19 supply and while it is now decent it could still stand improvement. It was not usable on the economy supply. This ARC 5 one has always had a hum issue and I intend to get rid of it if possible. I already checked the diodes , it was first thing I did actually and inspected the caps. They are relatively new and not old nos stuff. If I have to replace them at the end of this I will but I think they re good. I have spares , but these are better quality then the spares so I will take all this info onto account as I poke through each step.

Hi Robert,

As you know, the "Economy Power Supply" design uses a full-wave bridge around the full winding of tapped HV secondary, with Hi B+ off the common cathode node of the bridge, and LV B+ off the center-tap.

In a bridge rectifier, two of the diodes have a common cathode, so any "full wave" (i.e., single-filament, dual plate) rectifier tube can be used within its ratings. The other two diodes have a common anode, and the cathodes go to separate nodes. So, a common cathode tube won't work here. A pair of filamentary-type rectifier tubes could be used, but that means 3 separate filament windings just to light all the rectifier tubes. A rectifier tube with an indirectly-heated cathode like the 6X5 saves a winding so that only 2 windings are necessary to light the tubes in the bridge, since the cathodes in the 6X5s are adequately insulated from the heater so that the heaters can be connected together and run from a common winding. Also, the 6.3V winding used for the 6X5s can also be employed to light other tubes with 6.3V heaters in the gear being run from the supply.

73,
-Larry/NE1S

Here's a little write up to help understand the economy power supply:
http://w0vlz.blogspot.com/2013/11/more-about-power-supply-for-1939.html
Click on the diagram to see how it works as both a full wave bridge
rectifier and with center tapped full wave rectification.

Thanks to all who added input. Es machts nichts jetz because the parts came today and I just finished my mods a few minutes ago. Nervously I turned it on. No smoke. Always a good start! :>). So I hooked it up on CW (with a key.0 On the in shack monitor (A DX394 from RS) No perceptible hum. So I unplugged the key and plugged in the modulator. Same deal , no perceptible hum of any kind. My mod was I tore everything out back to the transformers. I made up an resistor, wire wound assembly right at the input , a pair of 172 ohm 10 watters I had in parallel. (to cut reistance, not for power handling) and I also installed a .01ufd 1 kv cap across the AC input from the transformer to kill hash. I checked the bridge out and all was good so I reused it but bypassed everything with four more .01ufd caps. Then I doubled up on the electrolytics putting two 47 ufds in series with appropriate bleeder resistors and added a second set of caps beside the originals. since being on series hurts their effectiveness some although it may not have been significant as it is often done. (They have a 450 volt rating).
I junked the Low HV take off completely and built a voltage divivder network from 5w wire wounds for that. Three 27Ks in series and pulled the low Hv of the lowest and last joint between them. This keeps me from pushing the osc tube too hard. I left the choke in the neg lead but was ready to scrap it if needed however it is extremely quiet. If I can drag my sorry butt out of bed early tomorrow I will try to check into the OMRN (Mikes baby). Dave KA2J is used to my ARC5s sound so will give me a good comparison. Meanwhile anybody feel lucky here I am up for a trial before then. I am currently tuned up on 3700kcs but can go anywhere on the band as it is VFO controlled. Now if everything hangs together I am good to go. I wonder now if I should have used 10W resistors for the divider although I have seen 5W recommended for this exact purpose. the divieder is double connected B+ and B neg which give the PSU better stability.Here's hoping. I would have the XYL take a little drive with a portable like before but she is having her mid aft nap and I am crazy, not stupid. I can wait.

12889. 40m Hartley test or sked (newbie)

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-03-12 03:03:13 UTC
From: aflowers@frontiernet.net

Hi,
I'm Andy, K0SM, and I'm new to the group. I'm young enough that I was born into a safe, solid-state world of 12V regulated power and crystal based DDSs and until a couple weeks ago I had never build anything with a tube in it. So it might not sound like much, but I've conquered a lot of ignorance and fear in the last few weeks to come up with a 40m single-tube self-excited Hartley. I even went in head first and used bakelite mica caps and powered the thing with a 5R4 after buzzing out a mystery transformer in an old 60's era ISM carcass. (I have a "proper" type 80 in the waiting but no transformer for it at the moment.)
Anyway, I put it on the air last weekend for the first time and initially got a 525 (awsome!) and then a 579C report after adjusting the taps a bit. There's probably only so much I can do about the chirp without moving to a regulated supply. The tone is generally pretty clean to my ears when its adjusted. It sounds much better on 80m and I can get a little more power out (with the right coil) but that's probably just because the frequency is twice as forgiving. No OO cards have shown up, yet :-)
Would anyone be up for a 1929 QSO this weekend? I'd be interested to see how it sounds to someone who knows what the are listening to. I might be fun to hear another such transmitter on the other end. The only antenna I have up right now is a low 40m dipole, so daytime/early evening on 40m is probably best within 600mi or so of Rochester, NY.
Thanks,
Andy K0SM/2

Andy, welcome to the group. Im also new around here and also young. Well relatively, Im just starting to feel old at 27. But anyway lots of great info is passed along here in the group, and just like on the golf course, the "old timers" will show you how its done.

I have a Hartley with parallel 227's that I have a 40m coil for. I might be able to get it to behave on 40 for a qso. I check to group pretty regularly (young guys and our smartphones) so post when and where youre going to be and I'll have a listen. I bet Don will too, maybe I can work both of you.

It looks like I'll have some time to play tomorrow (Saturday) afternoon. My guess is it will be after 2pm. I'll post to the list around midday when I have a better idea and whoever shows up can do so. Where's the best place to operate? Around 7050? Above 7100? Don, does your TNT have a preference?
Matt, I heard you last night around 3560 when I was tuning up the 80m coil into the dummy load. I would have answered you had I had and antenna. I have a single 27 with about 270V key-down, and something around 1W out to the antenna. I haven't seen signs of overcoupled the antenna yet with the current arrangement, so I might try a few more turns on the antenna link to see if I can get to a couple more dB without the signal falling apart.
Andy K0SM/2

Hi Andy, and welcome! It's great to see younger folks like you and Matt "getting the bug" and joining us. I've got a pretty busy weekend planned, but I'll try to make some time around 2PM and get on between 7100 - 7115 with my TNT from my Maine QTH. Those frequencies seem to be less busy than lower in the band, and I think the TNT is happier there.

I'm kitting parts from my "stash" for a UX227 Harley to give to a friend (K1YSK) who has expressed interest in building one. I wonder what value of grid leak you found worked well with the '27?

Except for the OT switch, I found something nearly identical to this at a hamfest about 15 years ago. I used it as my first L-network for a 160m vertical.

I assumed mine was one-off homebrew, now I'm wondering if it was a surplus or commercial item, or perhaps from a handbook.

With my parallel 227's im using an 8k grid leak. Seems to work fine at 8-9 watts input. What about you Andy? I have a mess of 27's and 227's now, all globe envelope and one st. I wanted a surplus for...testing. The ST type tube takes the higher inputs better. I only use ST tubes if I have to. And I forgot, since my heath PS is acting funky I might have to whip something up to run the 227 Hartley.

Its very interesting to me what people did with their tubes back in the day. I have been collecting hard copy QST's and in 1924 a guy was testing his 6 parallel uv-202's with 2kv on the plates.

Larry,
I had a 12K and a 20K for the grid-leak in my meager junkbox and I tried both. I early on I used 50pf instead of the standard 250pf for the grid capacitor since that's what I had. One of the old handbooks said that the grid cap should be at least 10x the grid-cathode capacitance, and 50pf is right on the edge. It didn't seem to care either way as I had no problem getting the thing to oscillate other than some stability problems that I traced to a loose tuning capacitor...all part of the fun. To my astonishment the thing fired up on the first key press. I have the 12K/250pf arrangement in right now.
I more or less followed WA9FWA's schematic, but added a 300pf variable + 50pf fixed series arrangement for a bandspread in parallel with the big tuning cap that makes the effect of hand capacitance fairly small at 7MHz. (The few pf from your hand is scaled downlard by the low value fixed series cap). Without something like that getting it anywhere near on frequency was impossible since there's no shielding and the both sides of the tank are above ground. The bandspread still covers about 400 KHz...er, kc...but its not linear and is spread out much toward one end of travel. The tradeoff is an extra air variable instead of a vernier dial.

>
> Hi,
> I'm Andy, K0SM, and I'm new to the group. I'm young enough that I was born into a safe, solid-state world of 12V regulated power and crystal based DDSs and until a couple weeks ago I had never build anything with a tube in it. So it might not sound like much, but I've conquered a lot of ignorance and fear in the last few weeks to come up with a 40m single-tube self-excited Hartley. I even went in head first and used bakelite mica caps and powered the thing with a 5R4 after buzzing out a mystery transformer in an old 60's era ISM carcass. (I have a "proper" type 80 in the waiting but no transformer for it at the moment.)
> Anyway, I put it on the air last weekend for the first time and initially got a 525 (awsome!) and then a 579C report after adjusting the taps a bit. There's probably only so much I can do about the chirp without moving to a regulated supply. The tone is generally pretty clean to my ears when its adjusted. It sounds much better on 80m and I can get a little more power out (with the right coil) but that's probably just because the frequency is twice as forgiving. No OO cards have shown up, yet :-)
> Would anyone be up for a 1929 QSO this weekend? I'd be interested to see how it sounds to someone who knows what the are listening to. I might be fun to hear another such transmitter on the other end. The only antenna I have up right now is a low 40m dipole, so daytime/early evening on 40m is probably best within 600mi or so of Rochester, NY.
> Thanks,
> Andy K0SM/2

Hi Andy, and welcome! It's great to see younger folks like you and Matt "getting the bug" and joining us. I've got a pretty busy weekend planned, but I'll try to make some time around 2PM and get on between 7100 - 7115 with my TNT from my Maine QTH. Those frequencies seem to be less busy than lower in the band, and I think the TNT is happier there.

I'm kitting parts from my "stash" for a UX227 Harley to give to a friend (K1YSK) who has expressed interest in building one. I wonder what value of grid leak you found worked well with the '27?

73,
-Larry/NE1S

No, It tunes ok between those two so what works for you in that general range is ok. Be careful with tirns out (but try it for sure.) Mine dontlike a lot. usually one on 40 and 2 turns on 80m. Often less is more. We may be too close but depends on propagation. I think it is 30 to 35 miles across the lake and I am in about 12 miles from shore. but sometimes it is pretty good too so we will see. Matt i have heard here on my modern rig but want to work hiim in "the real world"
Dont worry about being oung. Believe me it doesn't last. Enjoy it while you can!

Right now I have all four children to myself and will until mid afternoon.
It looks like I should be free around 3pm today. I'll try to get on around 7110 around 3:00 EST. If I don't hear anyone on I'll just start calling CQ. If I get free earlier or later I'll update here.

Andy,

I'd recommend trying a few "CQ"s or "TEST"s sometime this afternoon just
to get a broader picture on how/where you are getting out. Check the
Reverse Beacon Network at
http://www.reversebeacon.net/dxsd1/dxsd1.php?f=0&c=k0sm&t=dx for
automated signal reports.

I should be QRV this evening with my 1928 MOPA in the 160M "Spring" Stew Perry contest. It is an "after-midnight", 29 QSO Party legal rig, running about 19W input / 11W output. Hope to catch some west of the Rockies stations if QRN cooperates. I worked about 7 EU stations with this rig last week using a Four Square TX antenna.

The contest exchange is your grid square, but if you don't want logged in the contest, just give me a call for a report / quick chat.

I have been working on a '03A amplifier stage for this rig, but results have been dismal so far. Note and chirp is terrible, but not much time to mess with it lately. Need to try some different coupling parameters (coupling cap value / 210 amp tank tap) and maybe a different '03A tank setup, currently a double ended coil, single section variable, series feed with coil tap bypassed. Thinking of doing a split variable like my 811 MOPA and/or parallel feed. It also seems to break into oscillation with certain tank settings; parasitic suppressors where installed on both grid and plate.

I am suspecting those are low freq oscillations... may be brought on by the homebrew RFCs, 1mH, 4in. L x 15/16 in dia. wound in three sections, #32 enameled.

Heard you pretty well, Andy. Signal improved a bit while you were working Don. I only heard Don a little here and there, and I didnt hear Lou at all.

I was running my 210 TNT. Wound a 40 meter coil for it. Easier than a supply for the Hartley's 227's.

Well that sure was fun. I could hear both Andy and Matt here before 3 when Andy QRTed for a few minutes. then I worked Andy on my 211 TNT. I could hear Matt but only on the beverage antenna but I could hear him regardless. Made a lot of recordings which I will sort thru and see what I got. Andy, Ur rig has that classic sound. Don't touch nothin!
Then I thought I put Big Bertha on (the 211 hartley) as she has a lot more output then the 211 TNT and bingo there was Larry hisself. I was answering him and I heard someone right on top of us but he had enuf signal and a distinct enough sound I finish when he came back restoring my confidance that he could hear me. Then I fired up cathode modulator and plugged it into the 211 TNT for a quick AM call. I guess no one heard that. Anyway. That was fun. I'll sort thru the recordings later tonight.

Thanks a bunch, everyone. I haven't had this much fun with a radio in a long time. It's certainly the most fun you can have per component--I think there are 10 on the board, including the series variable to get this thing to like a 50 ohm load.
Some of my project involves my old family history, as I recently learned my great grandfather was 1ATZ according to the 1920-24 callbooks (I think we still have his operator license dated 1914 somewhere). He's listed as having a "5 watt" transmitter in the 1924 callbook, so I'm getting some idea of what his stuff might have sounded like and what kinds of challenges he would have run into with these early oscillators. He didn't have the advantage of an SDR to assist him in tuning it up, however.
I think the next project is going to be to make this circuit a little more permanent without altering that old-timey sound too much.

Haha yes that was a good time, I thought you had blown a cap or something. My 756 proiii's scope helped me find you once your signal came up. Something I wont have when I put my big boy britches on and use a real receiver like the super wasp.

Don I should have stuck around Id like to hear your AM sigs. Though probably have to happen on 80. I've been playing with loop mod when I should be doing other things. I dont think my candlestick carbon mic responds very well. Im going to try an amp modulator doohickey thing with two 201-A's and a 171-A.

Aw come on Matt. I worked well into your area with my loop. Even sat in a round table with a group and W2VW. Running a 45 TNT. Show me your set up and I will help you with it. However you gotta do what makes U happy. Too much coupling , more then one turn and two close can really mess it up. Less is usually more. You are comfy with a sniffer. Same deal only a mic replaces the bulb. In fact that is exactly what is on my 45 TNT. one loop used for either mod or tuning or power indication.
If your wasp works well you may find you have given up nothing. Some old regen rigs are extremely good.
Anyway, I would like to try the cat mod on the TNT sometime but it is only 40M . The Hartley while more powerful is not as stable so there seemed little point in trying it with that. Anytime te band as good and anyone wants to give it a shot I am up for it. If the CW note can be well heard there is a reasonable chance the AM will come through decent.
I had the old No 19 going tonite making one contact before coming upstairs. Anyway it sure was a fun afternoon.

12916. However More testing

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-03-13 12:45:15 UTC
From: dulmagedon@...
Topic: 12916 Message: 12916
Attachments: 1 described; binary payloads are missing from this source WARC

After the success of yesterdays test session and frankly it couldn't have gone better it would be good if we could do a test now and then with each other.I know for a fact often we don't get nswers when operating because we have a bit of a wonky sound. (Ain't it wonderful!) however when a few of us go on we discover we are definately getting out and have a ball. Matt brought up modulating. Several of us including Matt have been playing with various forms of it. I have a 45hartley cathode modulated by a 01A posted above. I need a test on air with it but it isn't a several hundred mile rig so a day like yesterday would do well. Larry has one too, I believe plate modulated if I am right, Lou has a looper (And has done some DXing with it recently.) I have a loop that fits on my rat trap (which some of you have worked on CW) that parks the coil with its mic in a nesting spot and I holler down a cardboard tube so as not to wiggle it freq wise as holding the mic and the mic cord is one of the bigger problems when looping. (Don't move, just be as still as possible and speak). It has never had an on air test other then in the house. Then last week I plugged my homemade ARC5 modulator into my 211 TNT and was surprised how good it sounded here but I would like to see how it sounds talking to someone else. So if anyone is up for some more fun, I am ready to play. Just a normal old signal report like we did yesterday. It is amazing how much we accomplish when we all work together. Yesterday was as fun for me as any of the events. So Andy , thanks for putting us all up to it!
donVe3LYX
BTW I went through the recording. It is all there but spread out over a couple of hours. If I can figure out how to edit it a seperate it I will spread it around where it belongs. Can't believe I missed Lou?! Larry was just POUNDING in here. My ears are still sore.

Don, I agree on the testing regularly. Of course being new at this game Im still somewhat amazed when anyone comes back to me. Its a thrill. I am around most nights. I stick around 3.580-3.600 unless theres a wide clear spot below. I would like to try and work you and Lou at some point. But youre probably right about an op's tendency to pass by such a goofy signal. I also wonder what QST termed a "1928" signal really typically sounded like, and how improved the "1929" signal was. It would be great to hear actual period recordings.

On modulation...I will give the loop another go. My loop is two turns no. 8 wire and you better believe i ended up with it .5mm from the tank while screaming into the mic. Physical vibration of the mic, tapping it etc I can hear just fine. Just no voice reproduction. How exactly are you cathode modulating? Ive tried an audio transformer in the fil center tap...that didnt work.

Hi Matt,

Try tuning your AM receiver slightly off-frequency, one side or the other or the carrier, and see if you can hear the audio. Often there is a lot more FM than AM; hence slope detection must be used.

OK go to one turn in you loop. Move it with in a 1/2 inch and speak. It needs to be near the main coil. . I usually put mine at the opposite end to the antenna output. Use your "Schniffer licht" to find the best spot.
How am I cathode modulating.
My rigs are cathode keying, I key the B neg so I insert a tube between the B neg feed from the PSU and the cathode of the modulator . Ie B neg from the PSU goes to the cathode of the modulator tube outthe plate and into the cathode OSC or amplifier tube. Crudley put the modulator tube is inserted where the key normally goes. Power comes in the bottom (cathode heater circuit flys across the grid at what ever strength s being allowed at that moment hits the plate and continues on to the next tubes cathode. By biasing the modulator tube (I generally start with a 5 K resistor over from the B neg cathode connection of the same tube) The tube is at the ready for modulation I use a carbon mic (telephone ones are great BTW) a battery and a normal audio output transformer. The primary (Thick coloured insulated wires usually) becomes the seconadry and is connect one side to the Bneg ground spot alonng where the bias resistor is connected and the other end of that winding is connected to a .1 paper cap or equivalant and pumped into the modulating tubes grid.
The mic and the battery are hooked in series and connected to the other winding of the output transformer (thin wire no insulation usually) A push to talk switch (doorbell buttons work nicely) is recommended so the battery doesnt pass away when sitting.
In summary. the modulation tube (01A is my tube of choice) now controls the B neg voltage being applied to the cathode of the Transmitter and it varies directly with the speech input from the carbon mic producing a somewhat remarkable modulation. BTW When using our old tubes Ie 45 osc and 01a modulator you MUST use separate supplies for the heaters of the two tubes otherwise they are just hooked together and nothing will happen. When using it with modern tubes (indirectly heated it is not an issue provided the cathodes and heaters are not mutually grounded.
I hope that sheds some light on it. Email me direct if you want. VE3LYXatgmaildotcom.
I am going down now to play on 80M for the afternoon. I am starting of with the ARC 5 and its modulator somewhere.anywhere there is AM activity with in reasonable distance this afternoon. later around 4 pm I will fire up the loop rat trap. Perhaps around 3805 so all can play if they like. Any mode reply accepted.

I was just on 80M. Nobody there , and I mean nobody. However I checked propagation. (3330 CHU time signal)
Clear and strong so and is definately open and probably in good shape prop wise. That is the defining test from here. If I can hear CHU well then the band is usually pretty good. I have the ARC5 on 3805 . mostly i am checking out the revived power supply but I am using AM. later around 4 I will put on the one in the picture nd see of anyone hears it. The ratrap wont tune that high so I may try 3545 for a quick one. We are permitted that although I try to avoid going that far afield from traditional bounderies. I don't remember how high it tunes. I will save the 40m stuff for another time. (211 hartley on the arc5s modulator and the looped TNT , my first experiment in this mode. Hope someone is free. And if you need to test, go for it. I will be happy to listen.

Almost all of the west coast stuff was worked after 0400z. KV4FZ, KH6ZM, and GW3YDX were all worked within a 25 minute span starting at 0610z, GW near his sunrise. TX antenna with gain surely helps. QRN was very low, propagation just good, but not great. I basically stopped for the night at 0635z, though did briefly check back and made a couple Qs around 0734z before going to bed.

Evening all,
Those using the '227 tube for the BK...could you pass along B+ values.
Also I wonder how it compares with say a '01A on the low end and a
'10 on the high end...that is, pwr output, stability, any problems getting
it to work in the usual BK circuits, things to watch out for, etc. Also,
will it work with the same C/L tank values.
Thanks

Hi Bill,

Probably not more than 300V on the plate of a 227. The max operating conditions as a class A amplifier in the tube manual is for 250V.

That said, last week I made an adaptor and tried a 227 in my Hartley in place of the 841, with no circuit changes. With ~400V on the plate I was getting as much output as with the 841 - about 5 watts. There was no indication of color on the plate. For CW it's probably OK, but that's just a SWAG. I tried both an ST '27 and a globe UY-227 with the same results.

This is the exact reason I chose a single 27 for my first foray into 1929 designs. I could get one for under $10 including the shipping, and even better per tube than that if you buy a batch of them. (It was either that or save $5 and wait till summer hamfests). Moreover, the indirectly heated cathode is simple to power with a DC bench supply (what I'm doing) or wall wart, and probably saves the center-tap resistor. Speaking from experience, if you've never done anything with a tube and see this center tapped resistor arrangement and keying method you might get very confused. A separate heater and cathode make the functions clear and you start to "get it". I'm now in the process of sourcing a directly heated tube for another transmitter, and this seems to me to be a natural learning progression, even if it's not the historical one.
In fact, parallel 27's might be even easier for a newbie since 5V supplies are legion, and can probably be scrounged from an old computer carcass. Then you can just light the 2.5V filaments in series.
To the original thread, I've been using a 12K grid leak with my ST-style 27 and see between 30-40ma depending on exactly how things are adjusted. With my homemade PS using stuff I had, keydown plate voltage is in the ballpark of 260V, and a little over 300V key up (hence the "classic" chirp). I used what I had available, and that meant this unknown transformer which determined the plate voltage for me. I figured that was close enough, and if I destroyed the tube I spent <$10 to learning a lesson. Its cheaper than school.

Andy, that is almost the exact reason I went for the 227 tube in a Hartley first. It looked more intuitive and I didn't want to mess with the extra parts, center tapped resistance and bypass caps. I had tried a 201-A and couldn't get it to sound very good, but the 227 was great. I pretty quickly went to two in parallel for more power. I don't know at what point one begins to require parasitic chokes but I would like to build a 27 or 201-A rig with 4 or maybe 6 in parallel. Just because.

The picture is my old shack in progress, and is where I plan to operate the '29 stuff. The 227 Hartley MOPA arrangment on the far right will be dismantled and replaced by one of those great wooden towers with neat panels and large tubes.
